APPENDIX 3.3-A, APPENDIX D: BALLAST HAULING MEMORANDUM

Memorandum

To:	Gary Kennerley, HSR Alice Lovegrove, HSR
From:	Laura Yoon, ICF Kim Avila, ICF
Date:	February 23, 2019
Re:	**High-Speed Rail San Jose to Central Valley Wye Project Extent: Estimated Emissions from Hauling Ballast Material**

Introduction

Construction of the San Jose to Central Valley Wye Project Extent (project) would require a substantial amount of railroad sub-ballast and ballast material to serve as the foundation for the track alignment. This memorandum describes the methods used to: (1) determine two possible scenarios of material hauling that could occur during construction of the project, and (2) calculate criteria pollutant and greenhouse gas (GHG) emissions associated with the material hauling activities for each project alternative. The information presented in this memo is intended to be used as an initial estimate of criteria pollutant and GHG emissions associated with truck and rail trips from material hauling that would occur within the San Francisco Bay Area Air Basin (SFBAAB), the North Central Coast Air Basin (NCCAB), and the San Joaquin Valley Air Basin (SJVAB). The actual distances and quantities associated with material hauling activities for the project are not known at this time, but this memo reflects a reasonable estimate of these activities given currently available information.

Table 1 shows total ballast and sub-ballast requirements for the project alternatives based on construction data provided by the project engineering team, AnchorCM (Scholz pers. comm.).

Table 1. Material Quantities by Alternative (cubic yards)

Material Type	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Ballast	273,000	518,000	297,000	647,000
Sub-ballast	447,000	829,000	477,000	1,035,000
Total	720,000	1,347,000	774,000	1,682,000

Quarries Evaluated

A list of all active quarries in California was obtained from the California Department of Conservation, Division of Mine Reclamation's interactive Mines Online (MOL) map (California Department of Conservation 2017). Quarries were filtered for those supplying a primary commodity that could potentially be used for ballast material (rock or sand and gravel), and those quarries that are in the air basins nearest to the project (SFBAAB, NCCAB, and SJVAB). Quarries with 200 or more acres of permitted area were considered to be of sufficient size to effectively serve the demand, consistent with the analysis approach taken for the Bakersfield to Palmdale Project Section (URS/HMM/Arup 2012).

Based on these criteria, the list of all active quarries in California was narrowed down to 11 quarries. It was assumed that the fewest possible quarries would be used for efficiency, and that the selection of quarries would differ through the project based on proximity to transportation infrastructure. Four quarries were identified to serve the San Jose Diridon Station Approach and Monterey Corridor Subsections, and two quarries were identified to serve the Morgan Hill and Gilroy Subsection. These two quarries, as well as an additional quarry in the SJVAB, would also serve the Pacheco Pass Subsection. Five quarries were identified to serve the San Joaquin Valley Subsection.

All selected quarries were evaluated using the following criteria:

1. Distance to the project in rail miles.
2. Distance from the quarry to the nearest railhead for transport (via roads).
3. Truck hauling distance (road miles) to project work sites through the SFBAAB, NCCAB, and SJVAB.

Table 2 shows the results of these inquiries. Distances were measured to the centerpoint of each subsection.

Table 2. Quarry Information

Quarry Name (Air Basin)	San Jose Diridon Station Approach		Monterey Corridor		Morgan Hill and Gilroy		Pacheco Pass		San Joaquin Valley	
	Rail Miles[1]	Road Miles[2]	Rail Miles[1]	Road Miles[2]	Rail Miles[1]	Road Miles[2]	Rail Miles[1]	Road Miles[2]	Rail Miles[1]	Road Miles[2]

Vernalis (SJVAB)	–	–	–	–	–	–	–	–	N/A	49

N/A = values represent quarries with no visible railhead.

– = Quarry not assumed to supply ballast for the subsection.

[1] Measured by Regional Consultant staff from each railhead, following the rail tracks, to the centerpoint of the alignment, using Google Earth imagery.

[2] Measured by Regional Consultant staff from each quarry to the centerpoint of the alignment using Google Earth directions.

Methodology for Developing Ballast Hauling Scenarios

The actual hauling scenarios that would take place during construction are not known at this time. Accordingly, the following two potential total hauling scenarios for ballast and sub-ballast material for the four project alternatives were developed for the quarries listed in Table 2.

- **Scenario 1**—All ballast and sub-ballast materials from quarries would be hauled by truck. This scenario represents the maximum emissions scenario for truck hauling.
- **Scenario 2**—All ballast and sub-ballast materials from quarries without rail or where rail would be infeasible would be hauled by truck. All ballast and sub-ballast materials from quarries with rail would be hauled by rail. Rail was considered infeasible if there was determined to be no direct route of train tracks from the quarry to the project. This scenario represents the maximum emissions scenario for rail hauling.

These scenarios were developed to provide a reasonable range of potential criteria pollutant and GHG emissions that might be generated by material hauling activities. The scenarios characterize a range of supply from the different quarries, representing the maximum amount of haul activity for truck transport to a maximum amount of haul activity for rail transport. Each of the selected quarries in each subsection was assumed to supply an equal amount of ballast (i.e., for the San Jose Diridon Station Approach Subsection, each of the four quarries was assumed to supply one-fourth of the total amount of ballast and sub-ballast material required for the subsection).

Table 3 shows the amount of ballast and sub-ballast hauled by truck and rail under Scenarios 1 and 2 for each project alternative.

Table 3. Amount of Ballast and Sub-Ballast Material Hauled from Each Quarry for Scenarios 1 and 2 (cubic yards per year)

Considerations for the Criteria Pollutant and Greenhouse Gas Emissions Analysis

The material quantities shown in Table 3 were used to determine the pollutant emissions that would be generated within the SFBAAB, NCCAB, and SJVAB from hauling activities for each construction phase that requires ballast and sub-ballast material hauling. The criteria pollutants evaluated were carbon monoxide (CO), nitrogen oxide (NO_X), particulate matter with a diameter of 10 micrometers or less (PM_{10}), particulate matter with a diameter of 2.5 micrometers or less ($PM_{2.5}$), reactive organic gases (ROG), and sulfur dioxide (SO_2). Analysts also evaluated carbon dioxide equivalents (CO_2e)—the contributions of carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O). Emissions were calculated by multiplying the mileage associated with each scenario by criteria pollutant and GHG emission factors for rail and truck hauling.

The distances between each quarry and the centerpoint of the alignment were estimated for rail hauling using Google Earth imagery. The distances between each quarry and the centerpoint of the alignments were estimated for truck hauling using Google Earth directions. The truck and rail hauling distances within each air basin were estimated using haul distances from Google Earth directions to the boundary of each air basin.

Total hauling distances associated with each scenario were calculated by multiplying the number of truck trips needed by the hauling trip distances associated with each scenario. The number of truck trips needed was determined by dividing the material quantities for each scenario by an assumed capacity of 20 cubic yards per truck. Material hauled by rail was converted to tons using a conversion factor of 1.3 ton of ballast/sub-ballast per cubic yard. Table 4 shows the emission factors used in the analysis. Rail emission factors are based on *Emission Factors for Locomotives* (USEPA 2009) and are presented in units of grams per ton-mile. Haul truck emission factors are from EMFAC2017 and are presented in units of grams per mile.

Table 4. Rail and Truck Emission Factors

Sources: EMFAC2017, USEPA 2009

Emission factors are presented for 2025 through 2028, which are the years in which ballast hauling would occur.

ROG = reactive organic gases

NO_X = nitrogen oxide

CO = carbon monoxide

PM_{10} = particulate matter with a diameter of 10 micrometers or less

$PM_{2.5}$ = particulate matter with a diameter of 2.5 micrometers or less

SO_2 = sulfur dioxide

CO_2 = carbon dioxide

USEPA = U.S. Environmental Protection Agency

[1] Emission units are grams per ton-mile. Based on a conversion factor of 484 ton-miles/gallon from the Association of American Railroads and grams/gallon emission factors from the USEPA's *Emission Factors for Locomotives* (USEPA 2009; American of Railroads 2016).

[2] Emission units are grams per mile. Based on EMFAC2017 regional fleet for heavy-heavy duty vehicles.

For this analysis, the significance of the criteria pollutant emissions associated with hauling activities is determined by comparing the emissions to the emissions thresholds relevant to the SFBAAB, NCCAB, and SJVAB, the basins in which all the quarries that were considered in this analysis are located. The applicable air districts in the SFBAAB, the NCCAB, and the SJVAB are the Bay Area Air Quality Management District (BAAQMD), the Monterey Bay Air Resources District (MBARD), and the San Joaquin Valley Air Pollution Control District (SJVAPCD), respectively. The federal and state air quality attainment status of the three air basins—which determines the General

Conformity *de minimis* thresholds that apply to the project—is shown in Table 5. The General Conformity *de minimis* thresholds that are applicable to the project are shown in Table 6, and the applicable air district California Environmental Quality Act (CEQA) thresholds are shown in Table 7. None of the local air districts (BAAQMD, MBARD, or SJVAPCD) has adopted a GHG emission threshold for construction-related emissions.

Table 5. Federal and State Attainment Status of the Study Area within the SFBAAB, NCCAB, and SJVAB

	SFBAAB		NCCAB		SJVAB	
Pollutant	**Federal**	**State**	**Federal**	**State**	**Federal**	**State**
Ozone (O_3)	N (marginal)	N	A/U	N-T	N (extreme)	N

PM_{10}: 82 lbs/day (exhaust only)		PM_{10}: 15 tons/year or 100 lbs/day[2]
$PM_{2.5}$: 54 lbs/day (exhaust only)		$PM_{2.5}$: 15 tons/year or 100 lbs/day[2]
		CO: 100 tons/year or 100 lbs/day[2]
		SO_X: 27 tons/year or 100 lbs/day[2]

Sources: MBUAPCD 2008; BAAQMD 2017; SJVAPCD 2015
BAAQMD = Bay Area Air Quality Management District
MBARD = Monterey Bay Air Resources District
SJVAPCD = San Joaquin Valley Air Pollution Control District
ROG = reactive organic gases
lbs = pounds
NO_X = nitrogen oxide
PM_{10} = particulate matter that is 10 microns in diameter and smaller
$PM_{2.5}$ = particulate matter that is 2.5 microns in diameter and smaller
CO = carbon monoxide
SO_X = sulfur oxide
CAAQS = California ambient air quality standards
NAAQS = national ambient air quality standards

[1] According to the MBARD CEQA guidelines, construction projects that temporarily emit precursors of ozone (i.e., ROG or NO_X) are accommodated in the emission inventories of state and federally required air plans and would not have a significant impact on the attainment and maintenance of state or federal ozone ambient air quality standard (MBUAPCD 2008). The MBARD guidelines have an exception if a project uses "non-typical equipment, e.g., grinders, and portable equipment"; the project would use standard construction equipment.

[2] The 100-pound-per-day threshold is a screening-level threshold to help determine whether increased emissions from a proposed project would cause or contribute to a violation of CAAQS or NAAQS. Projects with emissions below the threshold would not be in violation of CAAQS or NAAQS. Projects with emissions above the threshold would require an Ambient Air Quality Analysis to confirm this conclusion (SJVAPCD 2015).

Annual Hauling Activity Emissions

Maximum annual criteria pollutant and GHG emissions associated with hauling the ballast and sub-ballast material within the SFBAAB, NCCAB, and SJVAB are shown in Tables 8 through 10, respectively, for the two potential hauling scenarios. Ballast and sub-ballast hauling would occur in 2025, 2027, and 2028. In Tables 8 through 10, annual emissions are assessed against the General Conformity *de minimis* thresholds and annual CEQA thresholds applicable to the resource study area, respectively (see Tables 6 and 7).

As shown in Tables 8 through 10, ballast and sub-ballast hauling under all alternatives would not exceed any annual air basin or General Conformity *de minimis* thresholds. Ballast and sub-ballast hauling emissions have been incorporated into the larger project construction analysis presented in the *San Jose to Merced Project Section Air Quality and Greenhouse Gases Technical Report* (technical report) (Authority and FRA 2019) (see Chapter 7, Air Quality Effects Analysis).

Daily Hauling Activity Emissions

Daily maximum criteria pollutant emissions associated with hauling the ballast and sub-ballast material in the BAAQMD and MBARD are shown in Tables 11 and 12, respectively, for the two potential hauling scenarios. The highest average daily emissions in the SJVAPCD are shown in Table 13. Emission estimates were developed based on the hauling schedule, as provided by the project engineers (Scholz pers. comm.).

As shown in Table 11, ballast and sub-ballast hauling would exceed the BAAQMD's daily NO_X threshold under all project alternatives and both hauling scenarios. None of the project alternatives would exceed MBARD's daily PM_{10} CEQA threshold (see Table 12). All project alternatives under both hauling scenarios would exceed SJVAPCD's AAQA trigger for NO_X (see Table 13).

Ballast and sub-ballast hauling emissions have been incorporated into the larger project construction analysis presented in the technical report (see Chapter 7). Emissions more than BAAQMD's CEQA threshold would be offset to below the air district threshold level through implementation of AQ-MM#3: *Offset Project Construction Emissions in the San Francisco Bay Area Air Basin*.

Greenhouse Gas Emissions

Total GHG emissions (in terms of CO_2e over the entire hauling period) associated with hauling the ballast and sub-ballast material within the SFBAAB, NCCAB, and SJVAB are shown in Tables 8 through 10, respectively. The tables indicate total combined hauling emissions in all air basins would range from 3,449 to 6,877 metric tons CO_2e, depending on the project alternative and hauling scenario. Amortized GHG emissions over a 25-year period ranges from 138 to 275 metric tons CO_2e per year.

Ballast and sub-ballast hauling emissions have been incorporated into the larger project construction analysis presented in the technical report (see Chapter 8, Global Climate Change Effects Analysis). The short-term increase in construction-related emissions would be offset by long-term emissions reductions achieved during project operation.

CO = carbon monoxide
SO_2 = sulfur dioxide
CO_2e = carbon dioxide equivalent
AAQA = ambient air quality analysis
CAAQS = California ambient air quality standards
NAAQS = national ambient air quality standards

[1] Presents the average emissions estimate during a single day of construction in the highest emissions year. Average emissions are presented in SJVAPCD (rather than maximum), consistent with SJVAPCD (2015) guidance for correct application of their 100-pound-per-day AAQA screening criteria.

[2] The 100-pound-per-day threshold is a screening-level threshold to help determine whether increased emissions from a project would cause or contribute to a violation of CAAQS or NAAQS. Projects with emissions below the threshold would not be in violation of CAAQS or NAAQS. Projects with emissions above the threshold would require an AAQA to confirm this conclusion (SJVAPCD 2015).

Conclusion

The material hauling scenarios discussed in this memorandum represent possible ballast and sub-ballast material hauling activities for the project. While it is currently unknown which quarries and transport methods would be used, this memorandum provides a reasonable estimation of potential hauling scenarios and the corresponding criteria pollutant and CO_2e emissions.

Ballast and sub-ballast hauling would not independently exceed the General Conformity *de minimis* thresholds in the SFBAAB but would exceed the BAAQMD's NO_X CEQA threshold. Combined GHG emissions in all air basins would range from 3,449 to 6,877 metric tons CO_2e or 138 to 275 metric tons CO_2e per year over a 25-year project life.

Ballast and sub-ballast hauling emissions have been incorporated into the larger project construction analysis presented in the technical report. Emissions more than BAAQMD's CEQA threshold would be offset to below the air district threshold level through implementation of AQ-MM#3. GHG emissions would be offset by long-term emissions reductions achieved during project operation.

APPENDIX 3.3-A, APPENDIX E: LOCALIZED IMPACTS FROM CONSTRUCTION

APPENDIX E: LOCALIZED IMPACTS FROM CONSTRUCTION

1 INTRODUCTION

The California high-speed rail (HSR) program would include a wide variety of construction activities in numerous locations, extending from Scott Boulevard in Santa Clara through downtown San Jose and south to Gilroy across Pacheco Pass to Carlucci Road in Merced County (San Jose to Central Valley Wye Project Extent [project extent or project]). Because the total construction area would include laying of nearly 90 miles of track and three major tunnels with numerous portions built with various techniques (e.g., at grade, viaduct, berm, cut and fill, and possibly three concrete batch plants), analyzing the project as a whole is not practical. In general, analysts modeled representative sections of track for each construction activity within each subsection for long-term and short-term (less than 24-hour) air quality effects. Where feasible, the entire length of the subsection was modeled for all construction techniques. In addition, for short-term emissions, one construction activity may occur adjacent to another construction source type, and combined emissions would potentially be greater than either part alone. Based on the construction activities and engineering design, the following construction source types were evaluated for the potential to cause localized air quality effects:

- Berm
- At grade
- Aerial
- Trench
- Tunnel
- Cut and fill
- Operation of concrete batch plants to support construction

For each of these types of construction activities, maximum activities were determined, and air quality effects were evaluated. This appendix provides additional detail regarding the methods described in the *San Jose to Merced Project Section Air Quality and Greenhouse Gases Technical Report* (Air Quality and Greenhouse Gases Technical Report) to which this appendix is attached. This detail includes identification of the pollutants of concern, air quality modeling of the construction sites, determination of the modeled emission rates for the air dispersion modeling, and development of air quality modeling inputs and model output. Air dispersion modeling results were used to predict the ambient effects of criteria pollutant emissions and evaluate these effects with respect to the national ambient air quality standards (NAAQS) and California ambient air quality standards (CAAQS). Health risk calculations were also performed to evaluate the incremental cancer risks and acute and chronic noncancer health effects on receptors located near the construction work areas.

2 POLLUTANTS OF CONCERN

Criteria pollutants and toxic air contaminants (TAC)[1] were assessed for localized effects. The following criteria pollutants were considered in this analysis of potential localized effects:[2]

- Carbon monoxide
- Nitrogen dioxide (NO_2)
- Particulate matter (PM) smaller than or equal to 2.5 microns
- PM smaller than or equal to 10 microns
- Sulfur dioxide (SO_2)

TACs were analyzed for potential localized effects in terms of health risk. Sources of TACs include construction equipment exhaust and fugitive dust from concrete batch plant processes. The California Air Resources Board (CARB) and the California Office of Environmental Health Hazard Assessment (OEHHA) have identified TACs that may be emitted from these sources. Construction equipment exhaust may contain diesel particulate matter (DPM), and fugitive dust emissions from concrete batch plants may contain a number of toxic pollutants (in particular, heavy metals and sulfates). DPM has been identified by CARB as a TAC based on its potential to cause cancer and other adverse health problems, including respiratory illnesses and increased risk of heart disease. Heavy metals and sulfate associated with concrete batch plant emissions present potential carcinogenic and noncarcinogenic health risks.[3] Finally, some criteria pollutants pose acute and chronic health risks (such as NO_2 and SO_2). These pollutants are analyzed for both health effects and their effects relative to air quality standards.

Analyses were conducted that considered chronic (long-term) carcinogenic, chronic noncarcinogenic, and acute (short-term) health risks. These analyses were conducted following San Joaquin Valley Air Pollution Control District (SJVAPCD) guidance in the San Joaquin Valley and Bay Area Air Quality Management District (BAAQMD) guidance in the San Francisco Bay Area. OEHHA modeling guidance was followed for the health risk assessment. Further details on the cancer risk from DPM are discussed in Section 6.4.8, Construction Health Risk Assessment, of the Air Quality and Greenhouse Gases Technical Report.

[1] TACs (sometimes referred to as hazardous air pollutants) are noncriteria pollutants that pose health risk.

[2] Ozone and its precursors (reactive organic gases or volatile organic compounds) are classified as regional effects due to the atmospheric transport and chemical conversions that take place over long distances and time scales. Therefore, they were not analyzed in terms of localized effects. Lead emissions were not considered because the mass emissions are negligible and thus unlikely to exceed the ambient air quality standards. Lead was quantified as part of the TACs because it has health toxicity factors.

[3] Current analyses do not associate any combustion emissions, including DPM, with the concrete batch plants as combustion activities would not occur with batching activities.

3 MODELED CONSTRUCTION SITES

As described in Section 6.4.8 of the Air Quality and Greenhouse Gases Technical Report, the following construction source types were evaluated for the potential to cause localized air quality effects:

- Berm construction of the rail segment
- Aerial construction for an elevated rail segment
- At-grade construction for development of the rail segment
- Trench construction for a below-grade rail segment
- Tunnel construction and ventilation shafts for the rail segment
- Cut and fill for the rail segment
- Concrete batch plants to support construction

Not all subsections include all construction source types, but in each subsection, at least one modeling analysis was performed for at least one construction activity. A brief description of the approach and study area for each construction source type is provided in this section. More detailed modeling source parameters are provided in Section 6.4.8 of the Air Quality and Greenhouse Gases Technical Report. In addition to analysis of each of these seven construction source types, an analysis was conducted for potential effects from those short-term activities that could be co-located and occur simultaneously in each subsection. This approach assured that the maximum effect would be found, given the likelihood that construction activities could occur simultaneously at the same location.

Berm construction of the rail segment—The construction emissions associated with berm construction include phases such as utility relocation, earth excavation, concrete work preparation, retaining wall construction, form work, and track bed construction. Long-term emissions associated with berm construction were analyzed for the entire 90-mile project extent; however, for short-term emissions (maximum daily emissions) modeling over the entire 90-mile project extent would not be realistic because many combinations of adjacent construction activity types do not occur over the length of each subsection. Therefore, localized effects for short-term emissions in each subsection were evaluated for potential construction of 1,000-foot sections of track where concurrent construction activity types could take place. Anywhere from one to three track orientations were modeled depending on the alignment, with receptors located either adjacent or close to the rail line right-of-way.

Aerial construction for an elevated rail segment—The construction emissions associated with aerial (viaduct) construction include phases such as utility relocation; earth excavation; cast-in-place drilled pier construction; formwork for concrete work preparation, including aerial bridges; and concrete pouring. As in the case for berm construction, aerial construction was modeled for the entire 90-mile project extent for long-term activity; however, for short-term emissions (maximum daily emissions), modeling over the entire 90-mile project extent would not be practical because many combinations of adjacent construction activity types would occur over the length of each subsection. Therefore, localized effects for short-term emissions in each subsection were evaluated for potential construction of 1,000-foot sections of track where concurrent construction activity types could take place. Anywhere from one to three track orientations were modeled depending on alignment, with receptors located either adjacent or close to the rail line right-of-way.

At-grade construction of the rail segment—The construction emissions associated with at-grade construction include phases such as utility relocation, demolition, cast-in-place drilled pier construction, excavation for slurry wall, base slab formwork, and pouring of concrete slab and walls. As in the case for berm construction, the at-grade construction was modeled for the entire 90-mile project extent for long-term activity; however for short-term emissions (maximum daily emissions) modeling over the entire 90-mile project extent would not be practical because many combinations of adjacent construction activity types would occur over the length of each subsection. Therefore, localized effects for short-term emissions in each subsection were evaluated for potential construction of 1,000-foot sections of track where concurrent construction

activity types could take place. Anywhere from one to three track orientations were modeled depending on alignment, with receptors located either adjacent or close to the rail line right-of-way.

Trench construction of the below-grade rail segment—The construction emissions associated with trench construction include phases such as demolition, cast-in-place drilled pier construction, excavation for slurry wall and trench, base slab formwork, concrete slab and walls pouring. The locations for trench construction are well defined and limited to the Morgan Hill and Gilroy Subsection for Alternative 2. Therefore, localized effects for this subsection were evaluated for potential construction of the entire trench rail segment, with receptors located either adjacent or close to the rail line right-of-way.

Tunnel construction and ventilation shafts for the rail segment—The construction emissions associated with tunnel construction include phases such as tunnel boring,[4] muck handling (earth removal), forming and pouring of interior and upper walls and floors, and track bed construction. The locations for tunnel construction are well defined and limited to the Pacheco Pass Subsection and the Morgan Hill and Gilroy Subsection. Therefore, localized effects for these subsections were evaluated for potential construction of the entire tunnel rail segment. For the longest tunnel over the Pacheco Pass (13.6 miles), effects were evaluated at tunnel openings and for three ventilation shaft locations. The shorter tunnel as part of the Morgan Hill and Gilroy Subsection was evaluated for air quality effects at the tunnel openings.

Cut and fill for the rail segment—The construction emissions associated with cut-and-fill construction include phases such as land clearing, excavation, compact filling and slope finishing, and track bed construction. As in the case for berm construction, the cut-and-fill construction long-term activities were modeled for the entire 90-mile project extent; however, for short-term emissions (maximum daily emissions) modeling over the entire 90-mile project extent would not be practical because many combinations of adjacent construction activity types would occur over the length of each subsection. Therefore, localized effects for short-term emissions in each subsection were evaluated for potential construction of 1,000-foot sections of track where concurrent activity types could take place. Anywhere from one to three track orientations were modeled depending on alignment, with receptors located either adjacent or close to the rail line right-of-way.

Operation of concrete batch plants to support construction—Concrete batch plants and storage areas would be located near the west portal of the shorter tunnel and at the east and west portal of the longer tunnel that traverses the Pacheco Pass. The emissions from these plants were modeled at the proposed locations for these facilities. To capture the maximum effects, modeling results from the concrete batch plant were coupled with the maximum rail segment construction.

[4] The tunnel-boring machine would be electrically powered so there would be no direct on-site emissions.

4 CONSTRUCTION EMISSIONS AND EMISSION RATES

Air quality analyses were performed for two types of construction emission scenarios: (1) long-term (annual) mitigated emissions that characterized maximum annual average activity for each construction year (2022–2028) and source type of construction by subsection and (2) short-term mitigated emissions that characterized the maximum daily emissions for each subsection and source type of construction. The methods for modeling of each source type and determination of the maximum emission rate addressed both long-term and short-term emissions.

4.1 Long-Term

Long-term construction emissions were modeled as follows.

- Identify source type(s): embankment, aerial, tunnel, cut and fill, and trench
  - Embankment, aerial, and cut and fill were best characterized as area sources.
  - Tunneling activity was characterized as a horizontal point source at portal openings and a capped point source at ventilation shafts.
  - Trenching activity was modeled as an open-pit source.
- Determine the annual emissions for each source type and calculate the maximum annual criteria pollutant emissions for each of the 7 years (2022–2028).
- Use the information from the engineering construction analysis for the linear distance of construction for each source type and calculate the source-type emissions for the particular linear length for the AERMOD-modeled subsection.
- Express the emissions in units of grams per second (g/s) using an activity level of 250 days a year and 8 hours a day (except 365 days a year and 24 hours a day for the tunnel construction).
- Determine the maximum on-site emission density for each pollutant using the maximum year emission rate.
- Include the off-site activity (e.g., haul trucks) and include adjacent emission density for each modeled area source using a width of 12 feet. Maximum ballast emissions are included in the off-site modeling.

4.2 Short-Term

Short-term construction emissions were modeled as follows:

- Determine the maximum daily emissions for each construction activity subsection (e.g., berm activity concrete work and retaining walls may be done concurrently, as well as formwork and earthwork).
- For each subsection, determine the maximum daily emissions from among the 7 years (2022–2028)
- Each construction subsection is resolved to 1,000 linear feet within the engineering construction analysis. To determine the emissions density for the AERMOD air dispersion modeling (Section 5, Dispersion Modeling), divide the maximum daily emissions for each subsection by the total number of 1,000-foot segments.
- Express the emissions from pounds per day to g/s assuming 8 hours a day (except 24 hours a day for tunnel construction).
- Determine the emission density for each modeled subsection, model the subsection, and combine concentration results for activities that may occur in parallel.

Finally, the concrete batch plant fugitive dust contains several metals and sulfates that have chronic and acute health effects. These metals include arsenic, beryllium, cadmium, nickel, manganese, selenium, and lead. The emissions of these air contaminates from the concrete batch plants were based on the PM emissions and a speciation factor for each pollutant appropriate for concrete batching. The speciation factors were determined as the portion of the PM emissions composed of these pollutants based on the BAAQMD Permit Handbook on emission factors concrete batch plants (BAAQMD 2016).

5 DISPERSION MODELING

Because the project construction activities have the potential to cause adverse health effects, detailed dispersion modeling analyses were conducted to determine whether these effects would be significant. The U.S. Environmental Protection Agency's (USEPA) AERMOD atmospheric dispersion model was used to simulate physical conditions and predict pollutant concentrations near the construction work areas using historical meteorological data. This allowed for an assessment of the local air quality effects from the construction emissions.

AERMOD is the USEPA's recommended air dispersion model for near-field modeling from vented and unvented (fugitive) sources. The model uses hourly meteorological observations and emission rates to determine hourly average concentrations from which other averaging periods (3-hour, 24-hour, annual averages) are determined. The detailed information on the methods and data used to conduct the air dispersion modeling is summarized here and in Sections 6.4.8 and 6.4.9, Other Localized Construction Effects, of the Air Quality and Greenhouse Gases Technical Report.

5.1 Inputs

5.1.1 Model and Inputs

AERMOD (version 18081) was used to conduct the modeling analysis. All calculation inputs are identical between the simulations used in the health risk assessments and for air quality (those used for comparison of the NAAQS and CAAQS), except for site-specific health risk receptor placement, which was located at the nearest receptor locations. The modeling used terrain height information in the analysis. No removal through deposition of air contaminants was considered, and the FASTAREA computation method was used for all area sources. AERMOD's urban dispersion option was used in the analysis for locations between San Jose and Gilroy. The rural dispersion algorithm was used in the analysis for locations south and east of Gilroy and into the San Joaquin Valley.

5.1.2 Meteorological Data

AERMOD requires meteorological data as input into the model. These data are typically processed using AERMET and AERSURFACE, preprocessors to AERMOD. AERMET requires surface meteorological data, upper air meteorological data, and surface parameter data (supplied from AERSURFACE).

The SJVAPCD has meteorological datasets developed for use in air quality modeling within its boundaries. The dataset used in this analysis was based on data derived from a mesoscale meteorological model (MM5) that uses historical meteorological data to develop meteorological data where there are no airports (in this case, Los Banos). Five years of hourly meteorological data (2004–2008) were used in the Merced County portion of the analysis.

The BAAQMD has meteorological preprocessed data based on observations from San Jose International Airport for surface observations and Oakland International Airport for upper air data. Five years of meteorological data (2009–2013) were used in the analyses for the San Jose Diridon Station Approach and Monterey Corridor Subsections.

The BAAQMD had meteorological data available from an instrumented tower located in San Martin for the period 2010–2014. Use of this data required AERMET processing for use in the AERMOD model.

Meteorological data used in the creation of the San Martin AERMET data for input to AERMOD are shown in Table 1.

Table 1 Meteorological Data for AERMET Processing at the San Martin Site

Site ID	Site Name	Latitude (deg N)	Longitude (deg W)	Elevation (m)	Source of Data

deg N = degrees north
deg W = degrees west
m = meters
BAAQMD = Bay Area Air Quality Management District

The surface data for the San Martin site was available in the ONSITE format required by AERMET for the period 2010–2014. Upon the suggestion of the BAAQMD (Cordova pers. comm.; BAAQMD 2016), data from San Jose International Airport were used for cloud cover when processing the ONSITE data, precipitation data from the San Jose Climate Station were used to determine surface moisture conditions for use in AERSURFACE, and data from the Oakland upper-air site at Oakland International Airport were used to represent conditions aloft.

5.1.2.1 AERSURFACE Processing

The National Land Cover Dataset 1992 (NLCD92) (Vogelmann et al. 2001) was downloaded[5] and used with AERSURFACE (version 13016) to provide the surface parameters for the third stage of AERMET. The coordinates of the San Martin BAAQMD meteorological site were used to determine surface characteristics in AERSURFACE. AERSURFACE was run with specifications that the area was not arid and that the site was not at an airport. Per the BAAQMD's recommendation (Cordova pers. comm; BAAQMD 2016), five sectors were used for San Martin processing to account for variations in land cover near the measurement site:

- SECTOR 1: 48–186 degrees
- SECTOR 2: 186–237 degrees
- SECTOR 3: 237–284 degrees
- SECTOR 4: 284–342 degrees
- SECTOR 5: 342–48 degrees

The study radius for surface roughness was set at 1 kilometer. The monthly seasonal profile used is shown in Table 2.

Table 2 Monthly Seasonal Profile at the San Martin Site

Months	Season
November, December, January	Late autumn after frost and harvest or winter with no snow
February, March	Transitional spring with partial green coverage or short annuals
April, May, June, July	Midsummer with lush vegetation
August, September, October	Autumn with unharvested cropland

[5] http://landcover.usgs.gov/natllandcover.php

AERSURFACE was run separately specifying dry, average, and wet surface moisture, and the results were later used to create composite surface characteristics for the third stage of AERMET.

5.1.2.2 Determination of Dry, Average, and Wet Months

Based on recommendations from BAAQMD (Cordova pers. comm.; BAAQMD 2016) and information provided in the AERSURFACE users' guide, each month in the modeling period was classified as either dry, average, or wet, and this information was later used in Stage 3 of AERMET. The rainfall data for the San Jose Climate Station for the 30-year period ending 2015 were gathered, and 30-year monthly averages were computed for each month. The monthly statistics for a given month were not used in the average if more than 5 days of data were missing in a given month. The next step was to compute the ratio of the monthly precipitation total for a given month during the modeling period and the corresponding 30-year monthly average. If the ratio was less than 0.5, the month was designated as dry. If the ratio was greater than or equal to 0.5 but less than 2, the month was designated as average. If the ratio was greater than or equal to 2, the month was designated as wet. Table 3 provides the information for the moisture classification of the region.

5.1.2.3 AERMET

Version 15181 of AERMET was used to process the meteorological data. The first step used data from the Oakland upper-air soundings with the MODIFY option turned on. San Jose International Airport data were used for the SURFACE portion of the processing, and San Martin on-site data were used for the ONSITE portion. The missing flags were set per BAAQMD recommendations (Cordova pers. comm.; BAAQMD 2016) and are shown in Tables 4 and 5.

Table 4 AERMET Single-Value and Date/Time Variable Descriptions and QA Values

AERMET Name	Description	Units	Missing Indicator	Lower Bound	Type	Upper Bound
OSDY	Day		-9	1	<=	31
OSMP	Month		-9	1	<=	12
OSYR	Year		-9	0	<=	99
OSHR	Hour		-9	0	<=	24
PAMT	Precipitation	cm	999	0	<=	100
INSO	Insulation	watts/square meter	9999	0	<	1250

Table 5 AERMET Multi-value Variable Descriptions and Quality Assurance Values

AERMET Name	Description	Units	Missing Indicator	Lower Bound	Type	Upper Bound
TT01	Temperature	degrees Centigrade	99	-30	<	46
WS01	Wind speed	meters / second	999	0	<	50
WD01	Wind direction	degrees from north	999	0	<=	360
RH01	Relative humidity	percent	999	0	<=	100
DP01	Dew-point temperature	degrees Centigrade	99	-65	<	35
SA01	Standard deviation, horizontal wind	degrees	999	0	<	104

Sources: Cordova pers. comm.; BAAQD 2016; USEPA 2016

The second step was a simple merging of the quality assurance files produced from step one. The third step was to set the following options per BAAQMD suggestion (Cordova pers. comm.; BAAQMD 2016):

- SUBNWS option was turned off. REFLEV SUBNWS was not turned on, so entire substitution of all meteorological parameters was not used.
- METHOD CCVR SUB_CC was turned on; therefore, cloud cover substitution from the NWS site was performed.
- METHOD TEMP SUB_TT was turned on; therefore, temperature substitution from the NWS site was performed.

This final step was repeated separately for each of the 5 years. The surface characteristics portions of the input files were created by using the AERSURFACE output corresponding to the moisture characteristics of each month and year. The output message and report files were checked for error messages. The error messages were examined and the errors were corrected when possible. Warning messages were also reviewed. In some cases, changes in inputs were made based on warnings (e.g., discrepancies in elevations provided in site list files and in the actual data). In other cases, they were left unchanged (e.g., variations in elevations throughout the data files). Other warnings regarding missing data and substituted data were noted, but no changes were made to the data.

- **Terrain—**Terrain information for modeling used terrain data available from the National Elevation Dataset at 1/3 arc-second database.
- **Receptors—**Receptors were modeled using a network of discrete receptors. Details on the spacing, height, and layout are provided in Sections 6.4.8 and 6.4.9 of the Air Quality and Greenhouse Gases Technical Report.
- **Source parameters—**Details on the source type configurations, release height, and spatial dimensions are provided in Section 6.4.8 (Tables 6-6 and 6-7) of the Air Quality and Greenhouse Gases Technical Report. Construction is modeled as occurring 5 days per week with 8-hour days (250 days per year), except for construction of the tunnels, which occurs 7 days per week, 24 hours per day. For the non-tunnel emissions, AERMOD's HRDOW7 option was used to have emissions occur from 8:00 a.m. to 4:00 p.m., Monday through Friday.

5.2 Output Options

The dispersion model outputs hourly concentrations and these can be expressed in terms of different averaging periods, such as hourly, daily, and annual, in the same form as the air quality standard. The averaging times used for the ambient air quality standards and concentration thresholds are different for each pollutant. To compare the model results to the applicable ambient air quality standards and thresholds, criteria pollutant concentrations were calculated relative to the form of the air quality standard for the CAAQS and the NAAQS.

AERMOD output files and Hotspots Analysis and Reporting Program (HARP) Risk Assessment Standalone Tool (RAST) summary output files for the simulations are available upon request.

APPENDIX 3.3-A, APPENDIX F: POTENTIAL IMPACT FROM INDUCED WINDS

Potential Impact from Induced Winds for High-Speed Trains

PREPARED FOR: PMT

PREPARED BY: Mark Bennett/CH2M HILL, Avanti Tamhane/URS, Jonathan Tamimi/URS, Nathalia Prasetyo Jo/URS

COPIES: file

DATE: March 28, 2012

1.0 Background

The operation of a high-speed train (HST) causes aerodynamic forces such as airflow induced by these trains. These aerodynamic forces are influenced by factors such as train speed and distance from the train. The moving train creates a boundary layer along the length of the train and a wake behind the train that results in airflow in the general direction of the moving train. Turbulent fluctuations at the wake behind the train and sideways turbulent fluctuations accompany the airflow. Trains for the California HST system could reach a maximum speed of 220 miles per hour (mph).

This technical memorandum summarizes existing credible scientific evidence related to evaluating potential impacts from induced winds from HSTs on the environment. Specifically, it evaluates the potential for generating fugitive dust emissions and the potential for impacts to honeybees used to pollinate crops. It also includes a discussion of the relevance of incomplete or unavailable information to evaluating potential impacts.

2.0 Induced Wind

The Federal Railroad Administration (FRA) document, *Assessment of Potential Aerodynamic Effects on Personnel and Equipment in Proximity to High-Speed Train Operations* (FRA 1999), based on reviews of both the theoretical and experimental data available at the time, made conclusions on induced winds for trains with speeds of 150 mph or less. The document concludes that at a distance of 26 feet from a train traveling at 150 mph, the induced wind would be in the range of 10 mph to 40 mph. There is a range of induced wind speeds because of variations between trains and uncertainties in the experimental data.

A literature search for HST aerodynamics showed that most research in this area is concerned with determining the dynamic forces on the HST itself (Schetz 2001; Baker 2010) and has been conducted to facilitate the design of HSTs that are both safe and comfortable. In addition to that body of work, Chris Baker and Mark Sterling have produced recent papers on the induced wind caused by HSTs (Baker et al. 2001; Sterling et al. 2008; Jordan et al. 2010).

Sterling and Baker are both professors at the School of Civil Engineering at the University of Birmingham, Birmingham, UK. Their studies focus mainly on the impact of the induced wind (which they refer to as the "slipstream") on the safety of both workers and the public, waiting along the track. The paper *Modelling the Response of a Standing Person to the Slipstream Generated by a Passenger Train* (Jordan et al. 2010) illustrates that, due to the complex nature of the fluid flow around an HST (such as the shape of the train and the resultant turbulent fluid flow), there is no simple mathematical formula for the induced wind as a function of train speed.

During an August 2010 phone call, Professors Sterling and Baker said that due to European HST safety standards, the measurements of induced wind speed done in Europe are at distances of 9.8 feet or less (Sterling and Baker 2010). They said they considered two sets of induced wind profiles from the German

Intercity Connect HST (presented in Figure 18 of their recent paper [Sterling et al. 2008]) to be high-quality data that show the induced velocity as a function of the distance from the train (Sterling and Baker 2010).

Jordan et al., 2010, notes that the induced winds caused by an HST have three distinct components: (1) flow around the nose of the train, (2) flow along the train, and (3) flow in the wake of the train. As explained above, exact analytical solutions for these flow fields are not possible. This is especially true of the flow in the wake of the train. However, the average magnitude of the induced wind does diminish as the distance from the train increases. For the analysis in their most recent paper, the authors represent the induced velocity in the wake of the train as the product of an exponential and parabolic function of the distance with each function having a separate decay constant (Jordan et al. 2010).

Understanding that while an exact analytic solution to the induced winds from HSTs is not possible, it is nevertheless possible and useful to quantify certain aspects of the flow, such as average and peak speeds, in order to evaluate the potential impacts on the environment. Consequently, URS and CH2M HILL developed a methodology based on papers by Li and the FRA (Li, Renxian et al. 2008; FRA 1999) to estimate induced wind speed as a function of distance.

2.1 Methodology to Estimate Induced Winds

A study on the potential aerodynamic forces created by a passing HST on nearby objects (such as humans standing in the proximity of the train) are influenced by train speed, distance from the train, and the geometry of the train. *A Study of the Influence of Aerodynamic Forces on a Human Body near a High-Speed Train, Aerodynamics of Heavy Vehicles, Trucks, Buses, and Trains*, analyzed the maximum wind velocity around a human body, assumed to be a cylinder with a height of approximately 5.7 feet, for a specific train speed, as a function of human-train distance based on different train shape models (Li et al. 2008). The range of distance from train specified for Eq. 1 is between 0 feet to 11 feet.

$$u = \left(1.2319\right)^{0.072v-4} \times \left(0.4575d^2 - 3.5496d + 9.1545\right) \qquad \text{(Eq.1)}$$

Where:

u: the maximum wind velocity around human body near the train (mph).
d: human-train distance (feet).
v: train running speed (mph).

The analysis above is only appropriate for distance from the train up to 11 feet. If this equation is used for distance beyond 11 feet, then the results become invalid and another equation is needed. According to *Assessment of Potential Aerodynamic Effects on Personnel and Equipment in Proximity to HST Operations*, a train passing a station platform induces wind in its surroundings that diminishes with distance away from the train (FRA 1999). The paper computed induced wind speeds for two different train-passing speeds (100 mph and 150 mph), based on the high and low induced wind speed curves. The speed of the induced wind can be very high near the passing train but drops off sharply a short distance away. There are sufficient variations in the strength of the aerodynamic forces due to a train's design, such that a streamlined train with a slender nose, traveling at high speeds, creates aerodynamic forces that are no more severe than a train with a bluff nose traveling at slow speeds. If a train proposed for high-speed operation has a streamlined body design with a slender nose at the head and tail ends (such as the California HST traveling at 200 mph), it is possible that its favorable aerodynamic characteristics would offset the higher aerodynamic forces that would otherwise be created by its increase in speed. Therefore, a streamlined HST traveling at 220 mph could have an induced wind speed curve similar to a blunt-nosed train traveling at 150 mph, and the induced wind speed curve equation for a train traveling at 150 mph can be used to estimate wind speeds for an HST traveling at 220 mph by fitting a logarithmic equation to FRA-computed airflow for passing trains. This equation can be used to obtain the following model for distances from 11 feet to 30 feet):

$$u = -3.5515 \times \ln d + 8.8894 \quad \text{(Eq.2)}$$

Where:

u: the maximum wind velocity around human body near the train (mph).
d: human-train distance (feet).
This equation is only applicable for a train traveling at a speed of 220 mph

Based on the FRA-computed model, induced air flow beyond 30 feet would be significantly less because induced airflow tends to plateau (as shown in Figure 1). Again, a cylinder of approximately 5.7 feet was assumed to represent the human body for this analysis.

Eq. 2 cannot be applied to distances beyond 30 feet because the results become invalid, and literature searches have not shown any quantitative models to estimate induced wind speed past this distance. Therefore, Table 1 only lists the induced airflow as a function of distance from the train from 0 feet to 30 feet.

Table 1
Induced Air Flow from Passing Train Traveling at 220 mph

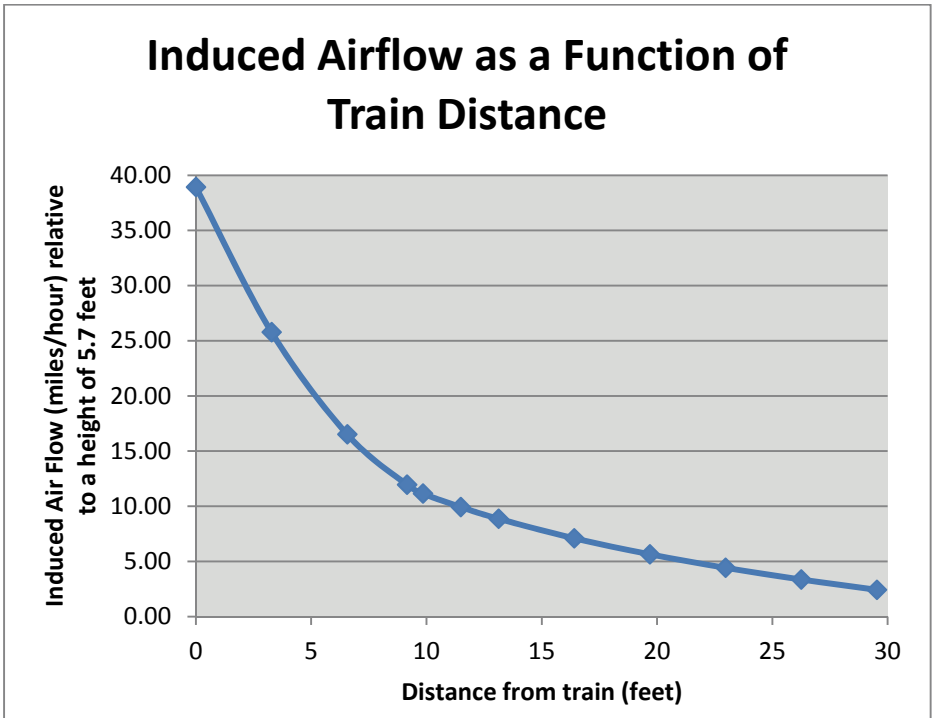
Distance from Train-Body[a] (feet)	Wind Speed u (mph)
0	38.94
3	25.79
7	16.53
9	11.96
10	11.16
11	9.93
13	8.87
16	7.10
20	5.65
23	4.43
26	3.36
30	2.43

[a] The values in Table 1 were developed with the methodology listed in Section 2.1, using the following equations:

For distance of 0 to 11 feet, the following equation is used to estimate induced air flow: $u = (1.2319)^{0.072v-4} \times (0.4575d^2 - 3.5496d + 9.1545)$ (Eq. 1).

For distance of 11 to 30 feet, the following equation is used to estimate induced air flow: $u = -3.5515 \times \ln d + 8.8894$ (Eq. 2).

Where:
u: the maximum wind velocity around human body near the train.
d: human-train distance.
v: train running speed (mph).



Note: Figure 1 was created using the methodology listed in Section 2.1, through the use of Eq. 1 and Eq. 2.

Figure 1
Induced Airflow as a Function of Train Distance
for a Train Traveling at 200 mph

2.2 Check of Induced Wind Speed Methodology

A number of assumptions are made regarding the methodology described in Section 2.1 to estimate the induced wind from the California HST System. As an independent check of the estimates from this approach, the data from the high-quality measurements of the Intercity Connect HST recommended by Sterling and Baker (2010) were used. In Table 1 of *A Study of the Slipstreams of High-Speed Passenger Trains and Freight Trains* (Sterling et al. 2008), distances at which induced velocities were measured are defined as, "Distance from train side or platform edge" in meters. From examining the data given in Figure 18 of that study, it was concluded that these data show that, for trackside measurements, the induced winds are between 5% and 10% of the speed of the train at a distance of 9.8 feet. Using this relationship, for an HST traveling at 220 mph, 5% and 10% of the train speed would be 11 mph (16.1 feet per second) and 22 mph (32.2 feet per second), respectively. These values bound the 16.37 feet per second (11.2 mph) estimate from Eq. 1 in Section 2.1 (shown in Table 1 below). The agreement between Eq. 1, which was derived from the *Assessment of Potential Aerodynamic Effects on Personnel and Equipment in Proximity to High-Speed Train Operations* (FRA 1999), and independent experimental measurements, is indicative of the validity of both approaches for estimating induced winds from the proposed California HST.

2.3 Induced Wind Speed and Elevation

While the wind speed generated by a train does vary relative to the elevation above the ground, Li et al. (2008) states,

> *The aerodynamic force acting on human body produced by train wind is related to many factors, such as train running speed, human-train distance, train head/tail shapes, smoothness of train surface, relative height between human and train, temperature and moisture of ambient air and so on. But the main factors are three: train running speed, human-train distance and train head/tail shape*

So distance from the train dictates the force and wind speed substantially more than the elevation does.

In the FRA paper, different trainsets were modeled to understand the impacts of high-speed use at existing stations in the Northeast Corridor (FRA 1999). One of the conclusions was that the "Induced airflow effects from a passing Acela trainset will be greater at 2.5 feet. above a platform than at 5.0 feet. above the platform, whether the platform is high-level or low-level." The paper also shows that, as the platform is elevated, wind speed and force are reduced at both 2.5 feet and 5.0 feet above the platform. This means that maximum wind speeds and forces modeled by the equations presented in this memo likely represent the highest wind speeds and forces created by the train, as the studies took the maximum force from the ground at a height of approximately 5.7 feet.

So, while the elevation relative to the ground does affect the induced wind speed from the train, the effect is small compared to the main factors (i.e., train speed, distance from train, and train head/tail shape), and this memo likely captures the maximum wind speed and forces produced by the train. For an elevated guideway, it is not anticipated that the wind speed and forces at-grade would be any greater than those calculated and presented in this memo.

2.4 Potential Impact of Induced Wind on Honeybees

Concern has been expressed that the wind gusts induced by the proposed HST might affect the bees that pollinate almond trees along the HST alignments. During an August 2010 phone call, Professors Sterling and Baker said they were not aware of any research done on the impact of HSTs on bees or pollination. (Sterling and Baker 2010). Right-of-way width for trains at-grade would be 100 feet and, according to design criteria, the nearest track would be at least 20 feet away from the edge of the HST right-of-way. Consequently, bounding the induced wind speeds at a distance of 20 feet or more was needed to evaluate the potential impact on bees pollinating almond trees.

The methods described in Section 2.0 are expanded upon in the following sections to estimate the wind gusts from a passing HST. These are compared to information about potential induced wind gusts and meteorological data for the Merced Regional Airport / Macready Field (KMCE), the Fresno Yosemite International Airport (KFAT), and the Bakersfield Meadows Field Airport (KBFL).

2.4.1 Meteorological Data

Meteorological data for Merced Regional Airport / Macready Field for the period of record of August 1998 to December 2008 (Western Regional Climate Center 2010a), Fresno Yosemite International Airport for the period of record of July 1996 to December 2008 (Western Regional Climate Center 2010b), and Bakersfield Meadows Field Airport for the period of record July 1996 to December 2008 (Western Regional Climate Center 2010c) were reviewed. The wind data for these three airports are very similar. Wind statistics are organized by month of the year:

- Merced Regional Airport / Macready Field:
  - The daily average wind speed ranges from 4.2 mph for November to 8.2 mph for June.
  - The daily average maximum 2-minute wind speed ranges from 12.1 mph for November to 16.7 mph in May.
  - The daily average peak gust, which is a maximum 5-second average, ranges from 15.0 mph in November to 21.3 mph in May.
  - The maximum daily average wind speed ranges from 10.9 mph for August to 22.1 mph for May.

  - The maximum 2-minute average wind speed range from 24 mph for September to 43 mph for December.
  - The maximum peak gust ranges from 29 mph for September to 51 mph for December.
- Fresno Yosemite International Airport:
  - The daily average wind speed ranges from 4.0 mph for December to 8.5 mph for June.
  - The daily average maximum 2-minute wind speed ranges from 11.5 mph for November to 17.7 mph in May.
  - The daily average peak gust, which is a maximum 5-second average, ranges from 14.2 mph for both November and December to 21.7 mph in May.
  - The maximum daily average wind speed ranges from 12.6 mph for July to 19.3 mph for March.
  - The maximum 2-minute average wind speed range from 25 mph for August to 38 mph for January.
  - The maximum peak gust ranges from 33 mph for both August and September to 46 mph for January.
- Bakersfield Meadows Field Airport (KBFL), CA:
  - The daily average wind speed ranges from 4.3 mph for November to 7.4 mph for June.
  - The daily average maximum 2-minute wind speed ranges from 12.4 mph for November to 17.3 mph in April.
  - The daily average peak gust, which is a maximum 5-second average, ranges from 14.7 mph for November to 21.4 mph in April.
  - The maximum daily average wind speed ranges from 9.4 mph for November to 22.3 mph for January.
  - The maximum 2-minute average wind speed range from 28 mph for July to 49 mph for February.
  - The maximum peak gust ranges from 33 mph for July to 57 mph for February.

2.4.2 Comparison with HST Induced Wind Gusts

Using the relationships from the German Intercity Connect HST data, induced winds from an HST traveling at 220 mph would be expected to range from 11 mph to 22 mph at 9.8 feet from the train. At 50 feet and 100 feet, the induced winds would be significantly less. As shown above in Table 1, at 20 feet the induced wind would be expected to be approximately 6 mph. A 1,400-foot-long train traveling at 220 mph would completely pass by an observer in less than 5 seconds; therefore a comparable wind statistic would be the daily average peak gust, where a peak gust is a maximum 5-second average wind speed. For Merced Regional Airport / Macready Field, Fresno Yosemite International Airport, and KBFL, the daily average peak gusts ranged from 15.0 mph to 21.3 mph, 14.2 mph to 21.7, and 14.7 to 21.4 mph, respectively. These ranges of speed are equivalent to the expected range of speeds of the induced winds at 9.8 feet from the train and two to three times greater than the 6 mph expected at 20 feet. Consequently, at 20 feet, 50 feet, and 100 feet from the train, the magnitude of the speeds of the induced winds would be expected to be less than and indistinguishable from naturally occurring wind gusts. Therefore, no impact on bee pollination from induced winds from the proposed HST would be expected to occur.

3.0 Wind-Generated Fugitive Dust Emissions from a Passing High-Speed Train

Wind erosion occurs when drag forces or shear stresses exerted by the wind exceed the retention forces acting on particles or debris at the surface. Once the minimum wind speed required to initiate particle motion (i.e., threshold friction velocity) has been reached, wind erosion occurs as a function of wind power or wind speed. The strong turbulent airflow along the sides of a moving train and the wake at the rear of the train may resuspend erodible debris and fine particulates from the surface of the surrounding impacted area, similar to particle resuspension from wind erosion. Attachment 1, *Wind-Generated Fugitive Dust Emissions from a Passing High-Speed Train* (URS 2010), provides more detail regarding methodology and findings.

3.1 Methodology

To estimate the fugitive dust emission from the particle resuspension, the AP-42 guidance Chapter 13.2.5 Industrial Wind Erosion (EPA 2006) was used to quantify the emission factor for wind-generated fugitive particulates emissions from a passing HST. This section presents the approach used to estimate the annual emissions of particulate matter smaller than or equal to 10 and 2.5 microns in diameter (PM_{10} and $PM_{2.5}$, respectively) from HST operation, based on the AP-42 guidance and project-specific data such as the impacted area.

Annual wind-generated fugitive dust/particulates emissions from a passing HST are a function of the impacted zone area and the wind erosion emission factor (per unit area). According to the AP-42 guidance, the wind erosion emission factor emission factor (in terms of mass per unit area) is a function of the disturbance frequency (where disturbance is defined as an action that results in the exposure of fresh surface material) in a year and erosion potential (which depends on friction velocity and threshold friction velocity).

3.1.1 Wind Erosion Emission Factor

Based on the AP-42 guidance, the emission factor for wind-generated dust emissions from the surface material of the impacted zone should be calculated as follows:

$$\text{Emission factor (g/m2):} \quad k\sum_{i=1}^{N} P_i \qquad \text{(Eq. 3)}$$

Where:

k = particle size multiplier
N = number of disturbances per year
P_i = erosion potential corresponding to the observed (or probable) fastest mile of wind for the i^{th} period between disturbances (grams/$feet^2$).

3.1.2 Particulate Emission Factor

As described in Eq. 3, the emission factor is a function of the disturbance frequency and erosion potential. The disturbance frequencies for various HST alignments were provided by the project engineers and are discussed in the *California High-Speed Train Project Merced to Fresno Section Air Quality Technical Report* (Authority and FRA 2012).

The erosion potential is the finite availability of erodible material (mass/area) on a surface. The AP-42 equations 1 and 3 for erosion potential were substituted into the Eq. 3 listed above, and the following emission factor (grams/feet^2) as a function of induced wind was derived:

$$k\sum_{i=1}^{N}\left[58\left(0.038955\text{u} - 0.19\right)^2 + 25\left(0.038955\text{u} - 0.19\right)\right]_i \quad \text{(Eq.4)}$$

Where:

k = particle size multiplier (0.5 for PM_{10} and 0.075 for $PM_{2.5}$).
u = induced wind speed at a certain height above the surface (mph)

3.1.2 Induced Wind Speed

As shown in Eq. 4, the emission factor can be expressed as a function of induced wind speed along the side of the train body. The induced wind profile could be estimated using Eq.1 from Section 2.1 of this memo.

3.1.3 Impacted Zone Area

The impacted zone area for the HST is defined as the surface area within both shoulders of the train track or within the right-of-way, at which the maximum friction velocity on the surface material is higher than the threshold friction velocity (i.e., the minimum wind speed required to initiate particle motion). The length of the impacted zone area is equal to the length of the at-grade track, and was obtained from the *California High-Speed Train Project Merced to Fresno Section Air Quality Technical Report* (Authority and FRA 2012)

3.2 Fugitive Dust Calculation

By integrating the emission factor function in Eq. 4 across the induced wind speed values within the impacted zone boundary area and multiplying the emission factor by the number of disturbance (N) and the particle size multiplier (k), the annual fugitive dust emissions from HST activity can be estimated.

Dust emissions generated by the wake at the rear of the train were not added to this calculation to avoid double counting. The erodible dust is already suspended in the air when the rear end of the train passes through, so additional turbulence or the rear wake will not contribute to more raised dust in the air.

The emission factor profiles over the distance from the train body are presented in Figure 2, and the emission factor over the impacted zone area is summarized in Table 2.

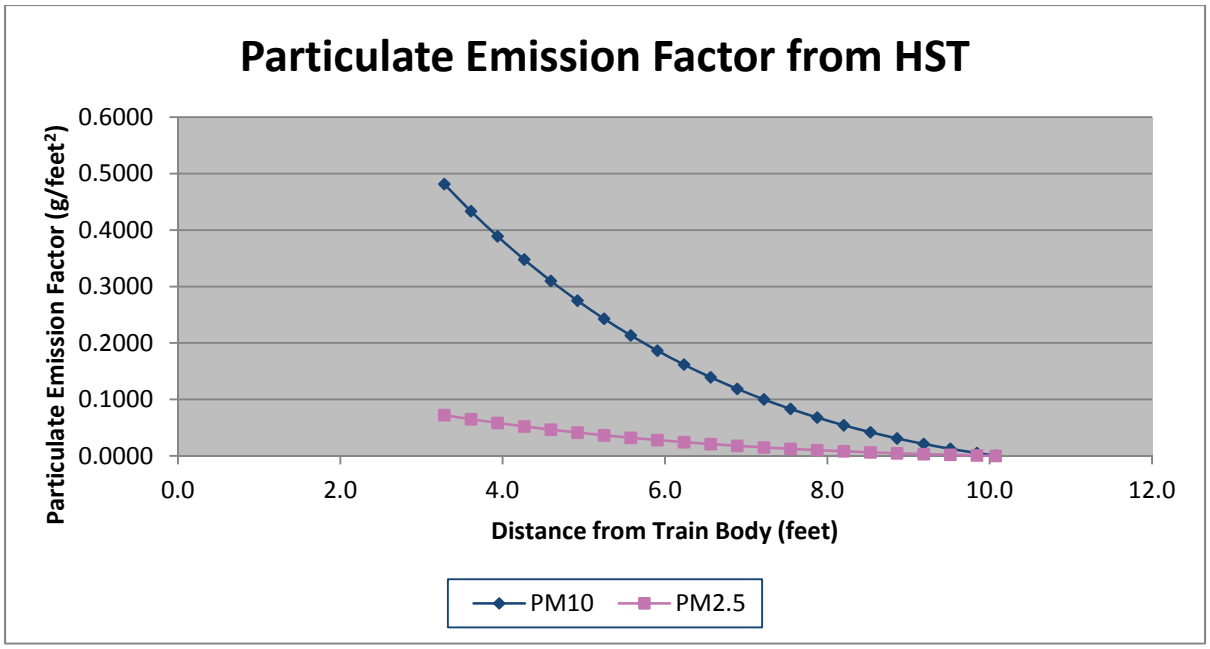


Figure 2
Particulate Emission Factor from Passing Train

Table 2
Emission Factor from Passing Train

Distance from Train-Body (feet)	Emission Factor (g/feet^2)	
	PM_{10}	$PM_{2.5}$
3.3	0.48	0.07
3.6	0.43	0.07
3.9	0.39	0.06
4.3	0.35	0.05
4.6	0.31	0.05
4.9	0.28	0.04
5.2	0.24	0.04
5.6	0.21	0.03
5.9	0.19	0.03
6.2	0.16	0.02
6.6	0.14	0.02
6.9	0.12	0.02
7.2	0.10	0.02
7.5	0.08	0.01
7.9	0.07	0.01

Distance from Train-Body (feet)	Emission Factor (g/feet^2)	
	PM_{10}	$PM_{2.5}$
8.2	0.05	0.01
8.5	0.04	0.01
8.9	0.03	0.00
9.2	0.02	0.00
9.5	0.01	0.00
9.8	0.01	0.00
10.1	0.00	0.00

The emission factor for wind-generated particulate emissions from a passing HST moving at 220 mph was calculated using the following steps:

- Using Eq. 1 and Eq. 4, integrate the emission factor over the distance of 3.3 feet to 10.1 feet from the train body.
- Multiply by particle size multiplier, k (0.5 for PM10 and 0.075 for PM 2.5)
- Multiply by the length of at-grade track length (impacted zone length).
- Multiply by 2 (to account for the left and right shoulders).
- Multiply by the number of disturbances per year, N

The trapezoidal rule for numerical integration is used to estimate the results for the particulate emission factor for a passing HST moving at 220 mph. For at-grade track lengths that range from 50 miles (264,000 feet) to 120 miles (633,600 feet), the PM_{10} fugitive dust ranges from 15.9 tons per year to 38.2 tons per year, and the $PM_{2.5}$ fugitive dust ranges from 2.4 tons per year to 5.7 tons per year. These emissions represent the total fugitive dust that will be suspended within the HST impacted zone area along the entire length of the alignment. As can be seen from Figure 2 and Table 2, the amount of fugitive dust suspended beyond 10.1 feet will be insignificant. Therefore, even though the train travels at speeds of 220 mph, it will not suspend herbicides, fungicides, or other harmful residues in the soil outside the HST-impacted zone area. The detailed results of these calculations can be found for various alignments in the *California High-Speed Train Project Merced to Fresno Section Air Quality Technical Report* (Authority and FRA 2012).

4.0 Incomplete and Unavailable Information

As noted earlier, an exact, analytical equation describing the induced wind from passing HSTs is unavailable because the technical means of obtaining it do not exist. Consequently, generally accepted scientific methods were used to extrapolate data from existing HST studies to approximate the induced winds expected from the California HST. The level of uncertainty in these estimates is sufficiently small that it is inconsequential to the evaluation of potential impacts from induced wind from the proposed California HST.

MEMORANDUM

To: **PMT**
From: Nathalia Prasetyo Jo (URS)
Date: July 12, 2010
Subject: **Wind-Generated Fugitive Dust Emissions from a Passing High-Speed Train**

Wind erosion occurs when drag forces or shear stresses exerted by the wind exceed the retention forces acting on particles or debris at the surface. Once the minimum wind speed required to initiate particle motion (threshold friction velocity) has been reached, wind erosion occurs as a function of wind power or wind speed.
Trains traveling at high velocity, such as the High-Speed Train, drag the surrounding air along the side of its body, which induces sideways turbulent fluctuations and rear wake. The strong turbulent airflow along the sides of a moving train and the wake at the rear of the train may resuspend erodible debris and fine particulates from the surface of the surrounding impacted area, similar to particle resuspension from wind erosion.

Methodology

To estimate the fugitive dust emission from the particle resuspension, the AP42 guidance Chapter 13.2.5 Wind Erosion was used to quantify the emission factor for wind-generated fugitive particulates emissions from a passing High-Speed Train. This memo presents the approach used to estimate the annual PM_{10} and $PM_{2.5}$ emissions from the High-Speed Train operation based on the AP42 guidance and current project description (at 15%design).
Annual wind-generated fugitive dust/particulates emissions from a passing High-Speed Train are a function of the impacted zone area and the wind erosion emission factor (per unit area). According to the AP42 guidance, the wind erosion emission factor emission factor (in terms of mass per unit area) is a function of the disturbance frequency (where disturbance is defined as an action that results in the exposure of fresh surface material) in a year and erosion potential (which depends on friction velocity and threshold friction velocity).
The influencing factors such as the impacted zone area, wind erosion emission factor, disturbance frequency, erosion potential and induced wind speed profile are discussed in detail in the following subsections.

Impacted Zone Area

The impacted zone area for the High-Speed Train scenario is defined as the surface area within both shoulders of the train track or within the right of way, at which the maximum friction velocity on the surface material is higher than the threshold friction velocity (the minimum wind

speed required to initiate particle motion).
The length of the impacted zone area is equal to the length of the at-grade track. Along the Fresno to Bakersfield alignment, the length of the at-grade track is approximately 43.56 miles (total track length subtracted by the elevated track section length)[1].
The width of the impacted zone is twice the distance from the beginning of the right of way area to the point where the corresponding maximum surface friction velocity generated by the induced turbulence is equal to the threshold friction velocity (assumed 0.19 m/s, based on the lowest value available for disturbed desert soil[2]). In this memo, the width of the impacted zone is referred to in terms of distance from the train body. The doubling of width was to account for the right of way area on the left and right side of the train track.
The boundary for the impacted zone is assumed to start at beginning of the right of way area (approximately one meter from the train body) and end at the distance where the corresponding friction velocity is equal to the threshold friction velocity. The surface area from the train body to the beginning of the right of way area was assumed to consist of non-erodible material because that area is within the embankment and rock ballast area.
To quantify the fugitive dust emissions generated by a High-Speed train passing at the speed of 220 mph, the emission factor needs to account for the induced wind speed profile and the distance within the impacted zone. Further discussion on the determination of the impacted zone boundary is presented in the induced wind speed section.

Wind Erosion Emission Factor

Based on the AP42 guidance, the emission factor for wind-generated dust emissions from the surface material of the impacted zone should be calculated as follows:

Emission factor (g/m2): $k\sum_{i=1}^{N} P_i$ (Eq.1)

Where:

k = particle size multiplier
N = number of disturbances per year
Pi = erosion potential corresponding to the observed (or probable) fastest mile of wind for the ith period between disturbances, g/m^2

As described in Eq.1, the emission factor is a function of the disturbance frequency and erosion potential. The approach and assumptions used to determine the disturbance frequency and erosion potential for the High-Speed Train operation scenario are presented as follows:

Disturbance Frequency

The disturbance is defined as an action that results in the exposure of fresh surface material. The number of disturbances per year during normal High-Speed Train operation is equal to the frequency of right of way access in a year (for maintenance or other purposes). The wind

1 The length of at-grade track was estimated based on the Fresno to Bakersfield HST Alignments Preliminary Draft Map, URS, 2010.
2 Watson, J.G, "Effectiveness Demonstration of Fugitive Dust Control Methods for Public Unpaved Roads and Unpaved Shoulders on Paved Roads", DRI Document No. 685-5200. IF2: August 2, 1996.

generated emission factor is dependent on the disturbance frequency because each time that the right of way surface area is disturbed, its erosion potential is restored.
The right of way surface area is currently expected to be disturbed twice monthly for visual inspection based on the operational and maintenance schedule of the High-Speed Train. Therefore, the erosion potential is assumed to be restored twice a month, which translates to 24 disturbances/year or N=24[3].

Erosion Potential

The erosion potential (P_i) is the finite availability of erodible material (mass/area) on a surface. For the wind erosion emission factor calculation, Pi is defined as the erosion potential corresponding to the observed fastest mile of wind[4] for the ith period between disturbances, and can be calculated as follows:

$P = 58 (u^* - u^*_t)^2 + 25 (u^* - u^*_t)$ (Eq.2)

$P = 0$ for $u^* < u^*_t$ (Eq.3)

Where:

u^* = friction velocity (m/s)

u^*_t = threshold friction velocity (m/s). Assumed 0.19 m/s, based on the lowest value available for disturbed desert soil.

Since there was no documentation for the friction velocity from High-Speed Train operation, induced wind velocity was used to estimate the friction velocity on the right of way surface based on the correlation given by Eq.4.

$$u_z = \frac{u^*}{0.4} \ln\left(\frac{z}{z_0}\right) \qquad (z > z_o) \qquad \text{(Eq.4)}$$

Where:

u_z = induced wind speed, m/s

u^* = friction velocity, m/s

z = height above test surface, cm

z_0 = roughness height, cm

0.4 = von Karman's constant, dimensionless

By substituting the friction velocity (u^*) from Eq.4 into Eq.2 and the erosion potential (Pi) from Eq. 2 into Eq. 1, the emission factor in Eq.1 can be expressed as a function of induced wind speed as shown in Eq. 5

3 Email correspondence between Thomas Baily (URS) with Arnold Luft (ARUP) dated July 6, 2010.
4 Fastest mile is the fastest one minute observed wind speed taken from a multiple register that contains a time record of the passing of each mile of wind

Emission factor (g/m^2): $$k\sum_{i=1}^{N}\left[58\left(\frac{0.4\,u_z}{\ln\left(\frac{z}{z_0}\right)}-u_t^*\right)^2+25\left(\frac{0.4\,u_z}{\ln\left(\frac{z}{z_0}\right)}-u_t^*\right)\right]_i \quad \text{(Eq.5)}$$

Where:
k = particle size multiplier (0.5 for PM_{10} and 0.075 for $PM_{2.5}$).
u_z = induced wind speed at a certain height above the surface (m/s). Note that emissions are only calculated in area with $u^* > u^*_t$. Because, when $u^* < u^*_t$, the erosion potential (P) is equal to zero.
u^*_t = threshold friction velocity. Assumed 0.19 m/s, based on the lowest value available for disturbed desert soil.
z = height above the surface (288 cm), based on 1/2 of the train height (1.88 m) and the average embankment height (3ft ~1 meter) with respect to the right of way5.
z_0 = surface roughness height (cm), assume 0.01 cm for the at grade right of way
0.4 = von Karman's constant, dimensionless

By substituting the assumptions above and other known parameters into Eq. 5, the equation can be simplified to.

Emission factor (g/m^2): $$k\sum_{i=1}^{N}\left[58\left(0.038955u_z-0.19\right)^2+25\left(0.038955u_z-0.19\right)\right]_i \quad \text{(Eq.6)}$$

Where:
k = particle size multiplier (0.5 for PM_{10} and 0.075 for $PM_{2.5}$).
u_z = induced wind speed at a certain height above the surface (m/s). Note that emissions are only calculated in area with $u_z > 4.88$ m/s (a substitute for $u^* > u^*_t$). Because, when $u^* < u^*_t$, the erosion potential (P) is equal to zero.

As shown in Eq. 6, the emission factor can be expressed as a function of induced wind speed along the side of the train body. By integrating the emission factor function in Eq.6 across the induced wind speed values within the impacted zone boundary (u_z) area, and multiplying the emission factor by the number of disturbance (24 times per year) and the particle size multiplier (k), the annual fugitive dust emissions from the High-Speed Train activity can be estimated. Dust emissions generated by the wake at the rear of the train were not added to this calculation to avoid double counting. The erodible dust is already suspended in the air when the rear end of the train passes through and therefore additional turbulence or the rear wake will not contribute to more raised dust in the air.

Induced Wind Speed Profile

The width of the impacted zone is twice the distance from the beginning of the right of way to the point where the corresponding maximum surface friction velocity generated by the induced turbulence is equal to the threshold friction velocity. To determine the distance where the corresponding maximum surface friction velocity generated by the induced turbulence is equal to the threshold friction velocity, a wind speed profile analysis is required.
A study on the potential aerodynamic forces created by a passing High-Speed Train on nearby

5 Track related measurements are based on Technical Memorandum, Typical Cross Sections for 15% Design TM 1.1.21 Appendix A: Two Track At-Grade Drawing and Project Description Summary (June 28, 2010)

objects (such as humans standing in the proximity of the train) are influenced by train speed, distance from the train, and the geometry of the train[6]. Li, et. al. analyzed the maximum wind velocity around a human body for a specific train speed as a function of human-train distance based on different train shape models:

$$u = (1.2319)^{0.072v-4} \times (0.4575d^2 - 3.5496d + 9.1545) \qquad \text{(Eq.7)}$$

Where:
u: the maximum wind velocity around human body near the train (m/s).
d: human-train distance (m).
v: train running speed (m/s).

The range of train speeds specified for Eq. 7 are between 55.56 m/s and 97.22 m/s (between 124 mph and 217 mph) with a human-train distance between 1.0 m and 3.5 m. This raises questions about the validity of this equation to estimate aerodynamic forces from a High Speed train traveling at a speed of 220 mph.
An induced wind speed profile comparison was graphed to determine the relative accuracy of using Eq 7 to estimated aerodynamic forces for train speeds of 220 mp compared to 217 mph (the upper bound of the train speed range for Eq 7). Figure 1 shows that Eq. 7 presents a similar trend when a train speed of 220 mph is used as compared to a train speed of 217 mph. Therefore Eq. 7 can be used to determine the induced wind speed profile as a function of distance from train body for train passing at 220 mph.

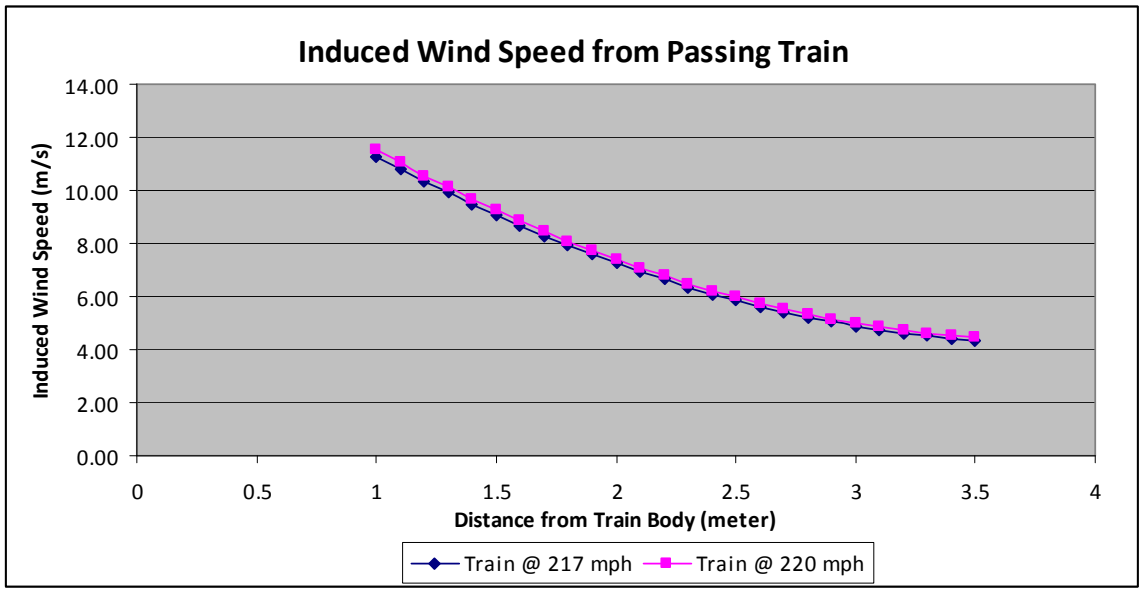

Figure 1. Wind Speed Profile Comparison from Train at 220 mph and 217 mph

6 Li, Renxian, et.al, "A Study of the Influence of Aerodynamic Forces on a Human Body near a High-Speed Train, Aerodynamics of Heavy Vehicles", Trucks, Buses, and Trains, 2008.

Emission Calculation

The emission factor profiles over the distance from the train body are presented in Figure 2 and the emission factor over the impacted zone area is summarized in Table 1.

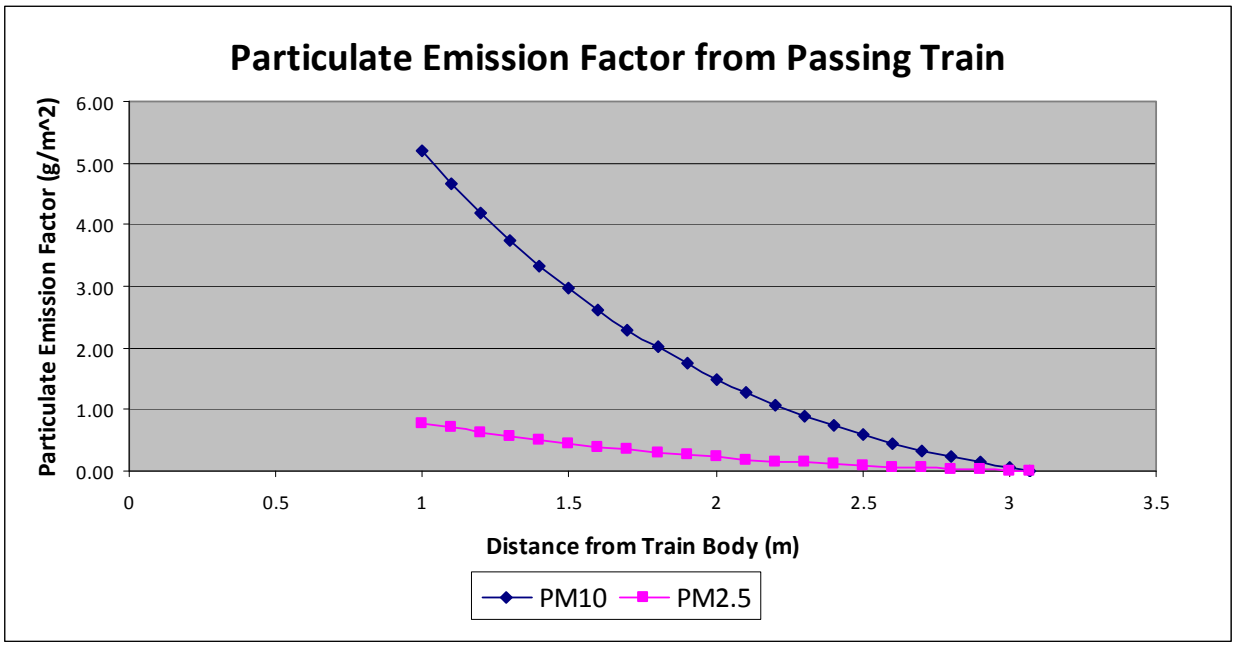

Figure 2. Particulate Emission Factor from Passing Train

Table 1. Emission Factor from Passing Train

Distance from Train-Body	Wind Speed (220 mph Train)	Friction Velocity	Erosion Potential	Emission Factor (g/m^2)	
(m)	u (m/s)	u*(m/s)	P (g/m^2)	PM_{10}	$PM_{2.5}$
1	11.53	0.45	10.37	5.18	0.78
1.1	11.03	0.43	9.33	4.67	0.70
1.2	10.56	0.41	8.38	4.19	0.63
1.3	10.10	0.39	7.49	3.75	0.56
1.4	9.66	0.38	6.68	3.34	0.50
1.5	9.24	0.36	5.92	2.96	0.44
1.6	8.83	0.34	5.23	2.62	0.39
1.7	8.45	0.33	4.60	2.30	0.34
1.8	8.08	0.31	4.02	2.01	0.30
1.9	7.72	0.30	3.48	1.74	0.26
2	7.39	0.29	3.00	1.50	0.22
2.1	7.07	0.28	2.56	1.28	0.19
2.2	6.77	0.26	2.16	1.08	0.16
2.3	6.48	0.25	1.79	0.90	0.13
2.4	6.22	0.24	1.46	0.73	0.11
2.5	5.97	0.23	1.17	0.58	0.09
2.6	5.74	0.22	0.90	0.45	0.07
2.7	5.53	0.22	0.67	0.33	0.05
2.8	5.33	0.21	0.46	0.23	0.03
2.9	5.15	0.20	0.27	0.14	0.02
3	4.99	0.19	0.11	0.05	0.01
3.07	4.88	0.19	0.01	0.00	0.00

As shown in Table 1, the corresponding friction velocity at the distance of 3.07 meters from the train body is equal to the threshold friction velocity of 0.19 m/s. Therefore, emission factor for wind-generated dust emissions should be calculated from the beginning of the right of way (1 meter from the train body) to the distance of 3.07 meters from the train body.

The emission factor for wind-generated particulate emissions from a passing High-Speed Train moving at 220 mph was calculated with the following steps:

- Using Eq. 6 and Eq. 7, integrate the emission factor over the distance of 1 meter to 3.07 meter from the train body.
- Multiply by particle size multiplier, k (0.5 for PM_{10} and 0.075 for $PM_{2.5}$)
- Multiply by 43.56 miles of at grade track length (impacted zone length).
- Multiply by two (to account for the left and right shoulders).
- Multiply by 24 disturbances per year (twice monthly).

Using the trapezoidal rule for numerical integration, the results for emission factor for wind-generated particulate emissions from a passing High-Speed train moving at 220 mph are 26.53 lb PM_{10} /miles of at grade track and 3.98 lb $PM_{2.5}$/ miles of at grade track. Multiplied by the

impacted zone length and disturbance frequency, the annual PM_{10} and $PM_{2.5}$ emissions from the High-Speed Train operation for the Fresno-Bakersfield section are 28.97 ton of PM_{10} /year and 4.3 ton of $PM_{2.5}$ /year.

APPENDIX 3.3-A, APPENDIX G: COUNCIL ON ENVIRONMENTAL QUALITY PROVISIONS COVERING INCOMPLETE OR UNAVAILABLE INFORMATION

Council on Environmental Quality (CEQ) Provisions Covering Incomplete or Unavailable Information (40 CFR 1502.22)

Sec. 1502.22 INCOMPETE OR UNAVAILABLE INFORMATION

When an agency is evaluating reasonably foreseeable significant adverse effects on the human environment in an environmental impact statement and there is incomplete or unavailable information, the agency shall always make clear that such information is lacking.

(a) If the incomplete information relevant to reasonably foreseeable significant adverse impacts is essential to a reasoned choice among alternatives and the overall costs of obtaining it are not exorbitant, the agency shall include the information in the environmental impact statement.

(b) If the information relevant to reasonably foreseeable significant adverse impacts cannot be obtained because the overall costs of obtaining it are exorbitant or the means to obtain it are not known, the agency shall include within the environmental impact statement:

1. a statement that such information is incomplete or unavailable;
2. a statement of the relevance of the incomplete or unavailable information to evaluating reasonably foreseeable significant adverse impacts on the human environment;
3. a summary of existing credible scientific evidence which is relevant to evaluating the reasonably foreseeable significant adverse impacts on the human environment; and
4. the agency's evaluation of such impacts based upon theoretical approaches or research methods generally accepted in the scientific community. For the purposes of this section, "reasonably foreseeable" includes impacts that have catastrophic consequences, even if their probability of occurrence is low, provided that the analysis of the impacts is supported by credible scientific evidence, is not based on pure conjecture, and is within the rule of reason.

(c) The amended regulation will be applicable to all environmental impact statements for which a Notice to Intent (40 CFR 1508.22) is published in the Federal Register on or after May 27, 1986. For environmental impact statements in progress, agencies may choose to comply with the requirements of either the original or amended regulation.

INCOMPLETE OR UNAVAILABLE INFORMATION FOR PROJECT-SPECIFIC MSAT HEALTH IMPACTS ANALYSIS

In FHWA’s view, information is incomplete or unavailable to credibly predict the project-specific health impacts due to changes in mobile source air toxic (MSAT) emissions associated with a proposed set of highway alternatives. The outcome of such

an assessment, adverse or not, would be influenced more by the uncertainty introduced into the process through assumption and speculation rather than any genuine insight into the actual health impacts directly attributable to MSAT exposure associated with a proposed action.

The Environmental Protection Agency (EPA) is responsible for protecting the public health and welfare from any known or anticipated effect of an air pollutant. They are the lead authority for administering the Clean Air Act and its amendments and have specific statutory obligations with respect to hazardous air pollutants and MSAT. The EPA is in the continual process of assessing human health effects, exposures, and risks posed by air pollutants. They maintain the Integrated Risk Information System (IRIS), which is "a compilation of electronic reports on specific substances found in the environment and their potential to cause human health effects" (EPA, https://www.epa.gov/iris/). Each report contains assessments of non-cancerous and cancerous effects for individual compounds and quantitative estimates of risk levels from lifetime oral and inhalation exposures with uncertainty spanning perhaps an order of magnitude.

Other organizations are also active in the research and analyses of the human health effects of MSAT, including the Health Effects Institute (HEI). A number of HEI studies are summarized in Appendix D of FHWA's Updated Interim Guidance on Mobile Source Air Toxic Analysis in NEPA Documents. Among the adverse health effects linked to MSAT compounds at high exposures are: cancer in humans in occupational settings; cancer in animals; and irritation to the respiratory tract, including the exacerbation of asthma. Less obvious is the adverse human health effects of MSAT compounds at current environmental concentrations (HEI Special Report 16, https://www.healtheffects.org/publication/mobile-source-air-toxics-critical-review-literature-exposure-and-health-effects) or in the future as vehicle emissions substantially decrease.

The methodologies for forecasting health impacts include emissions modeling; dispersion modeling; exposure modeling; and then final determination of health impacts – each step in the process building on the model predictions obtained in the previous step. All are encumbered by technical shortcomings or uncertain science that prevents a more complete differentiation of the MSAT health impacts among a set of project alternatives. These difficulties are magnified for lifetime (i.e., 70 year) assessments, particularly because unsupportable assumptions would have to be made regarding changes in travel patterns and vehicle technology (which affects emissions rates) over that time frame, since such information is unavailable.

It is particularly difficult to reliably forecast 70-year lifetime MSAT concentrations and exposure near roadways; to determine the portion of time that people are actually exposed at a specific location; and to establish the extent attributable to a proposed action, especially given that some of the information needed is unavailable.

There are considerable uncertainties associated with the existing estimates of toxicity of the various MSAT, because of factors such as low-dose extrapolation and translation of

occupational exposure data to the general population, a concern expressed by HEI (Special Report 16, https://www.healtheffects.org/publication/mobile-source-air-toxics-critical-review-literature-exposure-and-health-effects). As a result, there is no national consensus on air dose-response values assumed to protect the public health and welfare for MSAT compounds, and in particular for diesel PM. The EPA states that with respect to diesel engine exhaust, "[t]he absence of adequate data to develop a sufficiently confident dose-response relationship from the epidemiologic studies has prevented the estimation of inhalation carcinogenic risk (https://www.epa.gov/iris)."

There is also the lack of a national consensus on an acceptable level of risk. The current context is the process used by the EPA as provided by the Clean Air Act to determine whether more stringent controls are required in order to provide an ample margin of safety to protect public health or to prevent an adverse environmental effect for industrial sources subject to the maximum achievable control technology standards, such as benzene emissions from refineries. The decision framework is a two-step process. The first step requires EPA to determine an "acceptable" level of risk due to emissions from a source, which is generally no greater than approximately 100 in a million. Additional factors are considered in the second step, the goal of which is to maximize the number of people with risks less than 1 in a million due to emissions from a source. The results of this statutory two-step process do not guarantee that cancer risks from exposure to air toxics are less than 1 in a million; in some cases, the residual risk determination could result in maximum individual cancer risks that are as high as approximately 100 in a million. In a June 2008 decision, the U.S. Court of Appeals for the District of Columbia Circuit upheld EPA's approach to addressing risk in its two step decision framework. Information is incomplete or unavailable to establish that even the largest of highway projects would result in levels of risk greater than deemed acceptable (https://www.cadc.uscourts.gov/internet/opinions.nsf/284E23FFE079CD59852578000050C9DA/$file/07-1053-1120274.pdf).

Because of the limitations in the methodologies for forecasting health impacts described, any predicted difference in health impacts between alternatives is likely to be much smaller than the uncertainties associated with predicting the impacts. Consequently, the results of such assessments would not be useful to decision makers, who would need to weigh this information against project benefits, such as reducing traffic congestion, accident rates, and fatalities plus improved access for emergency response, that are better suited for quantitative analysis.

Due to the limitations cited, a discussion such as the example provided in this Appendix (reflecting any local and project-specific circumstances), should be included regarding incomplete or unavailable information in accordance with Council on Environmental Quality (CEQ) regulations [40 CFR 1502.22(b)]. The FHWA Headquarters and Resource Center staff, Victoria Martinez (787) 771-2524, James Gavin (202) 366-1473, and Michael Claggett (505) 820-2047, are available to provide guidance and technical assistance and support.

APPENDIX 3.3-B: DRAFT FEDERAL GENERAL CONFORMITY DETERMINATION

California High-Speed Rail Authority

San Jose to Merced Project Section

Draft Federal General Conformity Determination

November 2021

CALIFORNIA High-Speed Rail Authority

The environmental review, consultation, and other actions required by applicable federal environmental laws for this project are being or have been carried out by the State of California pursuant to 23 U.S.C. 327 and a Memorandum of Understanding dated July 23, 2019, and executed by the Federal Railroad Administration and the State of California.

EXECUTIVE SUMMARY

The California High-Speed Rail (HSR) system, proposed by the California High-Speed Rail Authority (Authority), will provide intercity, high-speed service on more than 800 miles of guideway throughout California, connecting the major population centers of Sacramento, the San Francisco Bay Area, the Central Valley, Los Angeles, the Inland Empire, Orange County, and San Diego. The San Jose to Central Valley Wye Project Extent (Project)[1], which is the focus of this General Conformity Determination, is a critical link connecting San Jose to the Central Valley portion of the HSR system at the Central Valley Wye in Merced County, which in turn connects to the portion of the system running north to Merced and south to Fresno and southern California.[2]

The General Conformity Rule, as codified in Title 40 Code of Federal Regulations Part 93, Subpart B, establishes the process by which federal agencies determine conformance of proposed projects that are federally funded or require federal approval with applicable air quality standards. This determination must demonstrate that a project would not cause or contribute to new violations of air quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emissions reductions towards attainment.

This draft General Conformity Determination documents the FRA's finding that the Project complies with the General Conformity Rule and that it conforms to the purposes of the area's approved State Implementation Plan and is consistent with all applicable requirements. This draft General Conformity Determination is being issued for public review and comment. The draft General Conformity Determination is available for public review on FRA's docket at https://www.regulations.gov/, Docket FRA-2021-X. Compliance is demonstrated as follows:

- Operations of the Project would result in a reduction of regional emissions of all applicable air pollutants and would not cause a localized exceedance of an air quality standard.
- While emissions generated during construction of the Project would exceed the General Conformity thresholds for nitrogen oxides in the San Francisco Bay Area Air Basin and San Joaquin Valley Air Basin, these emission increases would be offset through a new agreement with BAAQMD and an existing Memorandum of Understanding and Voluntary Emission Reduction Agreement with the San Joaquin Valley Air Pollution Control District, respectively.

[1] The Project Section has been evaluated in three extents: from San Jose to the western limit of the Central Valley Wye; the Central Valley Wye itself; and from the northern limit of the Central Valley Wye to Merced (i.e., the northern portion of the Merced to Fresno Project Section).

[2] As part of its first phase, the California HSR System is planned as seven distinct sections from San Francisco in the north to Los Angeles and Anaheim in the south.

1 INTRODUCTION

This draft General Conformity Determination for the San Jose to Central Valley Wye Section of the California High-Speed Rail (HSR) System (Project) (a portion of the San Jose to Merced Project Section [Project Section]) and was prepared consistent with the implementing regulations of Section 176 of the Clean Air Act (CAA). Section 176(c)(1) of the CAA prohibits federal agencies from engaging in, supporting, or providing financial assistance for licensing, permitting or approving any activities that do not conform to an approved CAA implementation plan. That approved plan may be a federal, state, or tribal implementation plan.

The CAA defines nonattainment areas as geographic regions that have been designated as not meeting one or more of the national ambient air quality standards (NAAQS)The CAA requires that each state prepare a State Implementation Plan (SIP) A maintenance plan must be prepared for each former nonattainment area that subsequently demonstrated compliance with the standards. The SIP is a state's plan for how it will meet the NAAQS by the CAA deadlines established by the CAA.

The General Conformity Rule is codified in Title 40 Code of Federal Regulations (C.F.R.)Conformity is defined as "upholding an implementation plan's purpose of eliminating or reducing the severity and number of violations of the NAAQS and achieving expeditious attainment of such standards." 40 C.F.R. Part 93 also establishes the process by which federal agencies determine conformity. This determination must demonstrate that the Project would not cause or contribute to new violations of air quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emissions reductions towards attainment. Since the Project is receiving federal funds through grants from the Federal Railroad Administration (FRA), it is an action that may be subject to the General Conformity Rule.

FRA prepared this draft General Conformity Determination for public review and comment. The final General Conformity Determination will be published after the public comment period. Analysis used for preparation of the *San Jose to Merced Environmental Impact Report (EIR)/Environmental Impact Statement (EIS)* was also reviewed and, where appropriate, integrated into this draft General Conformity Determination.

1.1 Regulatory Status of Resource Study Area

In November 1993, the U.S. Environmental Protection Agency (USEPA) two sets of regulations to implement section 176(c) of the CAA. The final transportation conformity regulations were approved on November 24, 1993 to address transportation plans, programs, and projects developed, funded, or approved under title 23 United States Code (U.S.C.) or the Federal Transit Act, 49 U.S.C Section 1601 et seq. (40 C.F.R. § 93 Subpart A). These regulations have been revised several times since they were first issued. While the Transportation Conformity regulations do not apply to the Project, many of the transportation planning documents developed under those regulations are helpful in understanding the regional air quality and planning status of the resource study area (RSA)The final general conformity regulations were approved on November 30, 1993. Because of the federal funding and potential safety and other approvals, the Project is subject to the general conformity regulations. The final general conformity regulations were approved on November 30, 1993. Because of the federal funding and potential safety and other approvals, the Project is subject to the general conformity regulations.

The RSA for the Project is the San Francisco Bay Area Air Basin (SFBAAB) San Joaquin Valley Air Basin (SJVAB), and the North Central Coast Air Basin (NCCAB). Figure 1 shows the Project footprint as it is situated in the three air basins. Planning documents for pollutants for which the RSA is classified as federal nonattainment or maintenance are developed by the Bay Area Air Quality Management District (BAAQMD), Monterey Bay Air Resources District (MBARD), San Joaquin Valley Air Pollution Control District (SJVAPCD), and the California Air Resources Board (CARB) and approved by the USEPA. Table 1 lists the planning documents relevant to the Project's RSA.

Table 1 Planning Documents Relevant to the Resource Study Area

Plan	Status
San Francisco Bay Area Air Basin	
2001 San Francisco Bay Area Ozone Attainment Plan for the 1-Hour National Ozone Standard	In a March 30, 2001, *Federal Register* notice (66 Fed. Reg. 17379), the USEPA proposed to make a finding that the Bay Area has not attained the national 1-hour O_3 standard. The USEPA proposed partial approval and partial disapproval of the 1999 Ozone Attainment Plan. On August 28, 2001, the USEPA took final action on its March 2001 notice, triggering a CAA requirement that a new plan be submitted within 1 year of the effective date of the USEPA's final action. The revised 2001 Ozone Attainment Plan included the necessary changes to address the USEPA's disapproval of the prior plan. In addition, to address the requirements triggered by the USEPA's finding of failure to attain, the plan included a new emissions inventory and commitments to adopt and implement additional control measures to attain the standard by 2006, the attainment deadline. It also included additional contingency measures in the event the Bay Area did not attain the standard by 2006.
2017 Clean Air Plan	Although not a federal planning document, the Bay Area 2017 Spare the Air, Cool the Climate (Clean Air Plan) provided a comprehensive plan to improve Bay Area air quality and protect public health. The Clean Air Plan defined a control strategy that the BAAQMD and its partners is implementing to: (1) attain all state and national ambient air quality standards; (2) eliminate disparities among Bay Area communities in cancer health risk from toxic air contaminants; and (3) reduce GHG emissions to protect the climate.
North Central Coast Air Basin	
2005 Report on Attainment of the California Particulate Matter Standards in the Monterey Bay Region	Although not a federal planning document, the plan fulfilled the requirements of Senate Bill 656 to reduce public exposure to PM. The plan outlines readily available, feasible, and cost-effective control measures for PM within the MBARD.
2007 Federal Maintenance Plan for Maintaining the National Ozone Standard in the Monterey Bay Region	This plan presents the strategy for maintaining the NAAQS for O_3 in the NCCAB. The NCCAB attained the 8-hour NAAQS in 2014.
2012–2015 Air Quality Management Plan	Although not a federal planning document, the Air Quality Management Plan is prepared triennially by the MBARD to document the region's continued progress toward meeting the state 8-hour O_3 standard.
San Joaquin Valley Air Basin	
2007 PM_{10} Maintenance Plan and Request for Redesignation	On September 25, 2008, the USEPA redesignated the San Joaquin Valley to attainment for the PM_{10} NAAQS and approved the 2007 PM_{10} Maintenance Plan.
2007 8-Hour Ozone Plan	On May 5, 2010, the USEPA reclassified the 8-hour O_3 nonattainment status of the San Joaquin Valley from "serious" to "extreme." The reclassification required the state to incorporate more stringent requirements, such as lower permitting thresholds, and implement reasonably available control technologies at more sources. The 2007 8-hour Ozone Plan contained a comprehensive and exhaustive list of regulatory and incentive-based measures to reduce emissions of O_3 and PM precursors throughout the San Joaquin Valley. On December 18, 2007, the SJVAPCD Governing Board adopted the plan with an amendment to extend

Plan	Status
	the rule adoption schedule for organic waste operations. On January 8, 2009, the USEPA found that the motor vehicle budgets for 2008, 2020, and 2030 from the 2007 8-hour Ozone Plan were not adequate for transportation conformity purposes. The next plan will address the USEPA's 2008 8-hour O_3 standard of 75 parts per billion.
2013 Plan for the Revoked 1-Hour Ozone Standard	On September 19, 2013, the USEPA approved the San Joaquin Valley's 2013 Plan for the Revoked 1-Hour Ozone Standard. Effective June 15, 2005, the USEPA revoked the federal 1-hour O_3 standard for areas including the SJVAB.
2015 Plan for the 1997 $PM_{2.5}$ Standard	On April 30, 2008, the SJVAPCD adopted the 2008 $PM_{2.5}$ Plan satisfying all federal implementation requirements for the 1997 federal $PM_{2.5}$ standard. Per guidance from the USEPA, the plan addressed the 1997 $PM_{2.5}$ standard under Subpart 1 of federal CAA Title 1, Part D (Subpart 1). Subsequently, in 2013, the D.C. Circuit Court ruled that the USEPA erred by solely using CAA Subpart 1 in establishing its $PM_{2.5}$ implementation rule, without consideration of the PM-specific provisions in CAA Title 1, Part D, Subpart 4 (Subpart 4). In June 2014, the USEPA classified the SJVAB as a "moderate" nonattainment area under Subpart 4. The USEPA recently reclassified the Valley as "serious" nonattainment effective May 7, 2015. The 2015 $PM_{2.5}$ Plan addresses the federal mandates for a "serious" nonattainment area related to the 1997 $PM_{2.5}$ standard.
2016 Moderate Area Plan for the 2012 $PM_{2.5}$ Standard	The 2016 Moderate Area Plan addresses the federal mandates for areas classified as "moderate" nonattainment for the 2012 $PM_{2.5}$ federal annual air quality standard of 12 micrograms per cubic meter
2016 Plan for the 2008 8-Hour Ozone Standard[1]	The District adopted the 2016 Plan for the 2008 8-Hour Ozone Standard in June 2016. This plan satisfies CAA requirements and ensures expeditious attainment of the 75 parts per billion 8-hour O_3 standard.
2018 $PM_{2.5}$ Plan	The 2018 $PM_{2.5}$ Plan provides a single integrated plan to attain the federal health-based 1997, 2006, and 2012 NAAQS. The plan builds upon comprehensive strategies already in place from previously adopted SJVAPCD attainment plans and measures.

1.2 General Conformity Regulations

On November 30, 1993, the USEPA promulgated final General Conformity regulations at 40 C.F.R. Part 93 Subpart B for all federal activities except highways and transit programs covered by Transportation Conformity. The regulations in Subpart B were subsequently amended in March 2010. Because the Project will not be funded or require approval(s) under Title 23 U.S.C. or the Federal Transit Act, 49 U.S.C Section 1601 et seq., the General Conformity requirements are applicable, rather than Transportation Conformity. In general terms, unless a project is exempt under 40 C.F.R. Section 93.153(c) or is not on the agency's presumed-to-conform list pursuant to 40 C.F.R. Section 93.153(f), a General Conformity Determination is required where a federal action in a nonattainment or maintenance area causes an increase in the total of direct

and indirect emissions of the relevant criteria pollutants and precursor pollutants that are equal to or exceed certain *de minimis* rates.

During the applicability analysis, the federal agency determines the following:

- Whether the action will occur in a nonattainment or maintenance area
- Whether one or more of the specific exemptions apply to the action
- Whether the federal agency has included the action on its list of presumed-to-conform actions
- Whether the total direct and indirect emissions are below or above the *de minimis* levels
- Where a facility has an emissions budget approved by the state or tribe as part of the SIP or Tribal Implementation Plan, the federal agency determines that the emissions from the Project are within the budget

The USEPA Guidance states that the applicability analysis can be, but is not required to be, completed concurrently with any analysis required under NEPA. The applicability analysis for this Project is described in Section 8, Applicability Analysis. If after the applicability analysis, the Federal agency concludes it should conduct a conformity determination, it may demonstrate conformity by one or more of several prescribed methods. These methods include:

- Demonstrating that the direct and indirect emissions are specifically identified in the relevant implementation plan
- Obtaining a written statement from the entity responsible for the implementation plan that the total indirect and direct emissions from the action, along with other emissions in the area, will not exceed the total implementation plan emission budget
- Fully offsetting the total direct and indirect emissions by reducing emissions of the same pollutant in the same nonattainment or maintenance area

2 CALIFORNIA HIGH-SPEED RAIL PROJECT

2.1 California High-Speed Rail System

The Authority, is responsible for planning, designing, constructing, and operating the HSR system. Its mandate is to develop an HSR system connecting the state's major population centers and coordinate with the state's existing transportation network, which includes intercity rail and bus lines, regional commuter rail lines, urban rail and bus transit lines, highways, and airports.

The HSR system will provide intercity, high-speed service on more than 800 miles of railroad throughout California, connecting the major population centers of Sacramento, the San Francisco Bay Area (Bay Area), the Central Valley, Los Angeles, the Inland Empire, Orange County, and San Diego. It would use state-of-the-art, electrically powered, high-speed, steel-wheel-on-steel-rail technology, including contemporary safety, signaling, and automated train-control systems, with trains capable of operating up to 220 miles per hour (mph) over a grade-separated, dedicated guideway alignment.

The FRA is responsible for oversight and regulation of railroad safety and implementation of the High-Speed Intercity Passenger Rail (HSIPR)As part of the HSIPR Program, the FRA is providing partial funding for the environmental analysis and documentation required under NEPA, CEQA, and other related environmental laws. Pursuant to U.S. Code Title 23 Section 327, under the NEPA Assignment Memorandum of Understanding between the FRA and the State of California, effective July 23, 2019, the Authority is the federal lead agency for environmental reviews for all Authority Phase 1 and Phase 2 California HSR System projects. The FRA performs Clean Air Act Conformity determinations and other federal approvals retained by the FRA under the NEPA Assignment Memorandum of Understanding.

In April 2012 and May 2014, respectively, the FRA and the Authority published the *Merced to Fresno Section Final EIR/EIS* (Merced to Fresno Final EIR/EIS) (Authority and FRA 2012)and *Fresno to Bakersfield Section Final EIR/EIS* (Fresno to Bakersfield Final EIR/EIS) (Authority and FRA 2014). The FRA issued the Record of Decision (ROD) for the Fresno to Bakersfield Project in June 2014. Both projects are within the SJVAB, and a General Conformity Determination was prepared as part of the environmental processes to comply with the CAA. The Merced to Fresno and Fresno to Bakersfield General Conformity Determinations include the Authority's commitment to offset all emissions to net zero through a Voluntary Emissions Reduction Agreement (VERA) between the Authority and the SJVAPCD. between the Authority and the SJVAPCD. Although the San Jose to Merced Project Section of the HSR system is independent of the other HSR system project sections for purposes of NEPA and CEQA analysis, certain construction activities may occur concurrently with construction activities for other project sections within the SFBAAB and SJVAB. Therefore, estimates of cumulative emissions, where available, have been presented in Section 13, Estimated Emission Rates and Comparison to *de minimis* Thresholds—Cumulative Analysis, of this document. These future emissions estimates have been included in this document in the interest of full disclosure of future construction emissions that may occur in the SFBAAB and SJVAB from other sections of the HSR system; each of these sections would undergo separate conformity determinations later.

2.2 California High-Speed Rail System—San Jose to Central Valley Wye Project Extent

The Project will provide HSR service between San Jose Diridon Station in downtown San Jose, with a Gilroy station in either downtown Gilroy or east Gilroy, and a station in downtown Merced. It will connect San Jose to the Central Valley portion of the HSR system at the Central Valley Wye in Merced County, which in turn would connect to the portion of the system running north to Merced and south to Fresno and southern California.

The Project is designed to allow trains to and from the Bay Area to transition smoothly from north-south to east-west travel with a minimum reduction in speed to achieve the Proposition 1A travel time requirement. Proposition 1A requires that the HSR system be designed to achieve a nonstop

service travel time of 2 hours and 10 minutes between San Jose and Los Angeles Union Station.[3] The Project follows existing transportation corridors to the extent feasible, as directed by Proposition 1A.[4]

The Project corridor is between Scott Boulevard and Carlucci Road and constitutes approximately 91 miles of the approximately 145-mile-long Project Section, which includes dedicated HSR track and systems, and station locations at San Jose Diridon and Gilroy; an MOWF in the Gilroy area, and an MOWS near Turner Island Road in the Central Valley. HSR stations at San Jose Diridon and Gilroy would support transit-oriented development, provide an interface with regional and local mass transit services, and provide connectivity to the South Bay and Central Valley highway network.[5] The Project begins at Scott Boulevard in Santa Clara. The HSR infrastructure and operations transition from the blended system between San Francisco and Santa Clara to a fully dedicated system north of the San Jose Diridon Station, either at Scott Boulevard in Santa Clara or near I-880; or, in the case of Alternative 4, the blended system extends to downtown Gilroy. The Project continues south and east from Gilroy, continuing east through the Pacheco Pass to the Central Valley to its end at Carlucci Road, the western limit of the Central Valley Wye.

The Project comprises the following five subsections:

- **San Jose Diridon Station Approach—**Extends approximately 6 miles from north of the San Jose Diridon Station at I-880 in San Jose or Scott Boulevard in Santa Clara to West Alma Avenue in San Jose. This subsection includes San Jose Diridon Station and overlaps the southern portion of the San Francisco to San Jose Project Section.
- **Monterey Corridor—**Extends approximately 9 miles from West Alma Avenue to Bernal Way in the community of South San Jose. This subsection is entirely within the city of San Jose.
- **Morgan Hill and Gilroy**—Extends 30–32 miles from Bernal Way in the community of South San Jose to Casa de Fruta Parkway/State Route (SR) 152 in the community of Casa de Fruta in Santa Clara County.
- **Pacheco Pass**—Extends approximately 25 miles from Casa de Fruta Parkway/SR 152 to I-5 in Merced County.
- **San Joaquin Valley**—Extends approximately 18 miles from I-5 to Carlucci Road in unincorporated Merced County.

The Authority has developed four end-to-end alternatives for the Project: Alternative 1, Alternative 2, Alternative 3, and Alternative 4. Each alternative consists of a variety of alignment and station options. It is estimated that construction of the Project would take approximately 7 years, with initiation of construction in 2022 and completion in 2028.

[3] Proposition 1A requires that the HSR system be designed to achieve a nonstop service travel time of 2 hours and 40 minutes between San Francisco and Los Angeles Union Station, including a 30-minute ride between San Francisco and San Jose (§ 2704.09(b)(4)).

[4] Proposition 1A requires that the HSR system be designed to operate on an alignment that follows existing transportation and utility corridors to the extent feasible (§ 2704.09(g)).

[5] *South Bay* refers to Santa Clara County.

3 AIR QUALITY CONDITIONS IN THE RESOURCE STUDY AREA

3.1 Meteorology and Climate

Air quality is affected by the rate and location of pollutant emissions and by meteorological conditions that influence movement and dispersal of pollutants in the atmosphere. Atmospheric conditions, such as wind speed, wind direction, and air temperature gradients, along with local topography, provide the link between air pollutant emissions and local air quality levels.

Elevation and topography can affect localized air quality. The Project extent crosses the SFBAAB, NCCAB, and SJVAB. Within the SFBAAB, temperatures in the Santa Clara Valley are warm on summer days and cool on summer nights, and winter temperatures are mild. Winds in the valley are greatly influenced by the terrain, resulting in a prevailing flow that roughly parallels the valley's northwest-southeast axis. Within the NCCAB, the semi-permanent high-pressure cell in the eastern Pacific, known as the Pacific High, is the basic controlling factor in the climate. The generally northwest-southeast orientation of mountainous ridges tends to restrict and channel the summer onshore air currents. In the fall and winter, the surface winds become weak, which can lead to pollutant transport from the SFBAAB and SJVAPCD into the NCAAB. Within the SJVAB, summer temperatures often exceed 100 degrees Fahrenheit, and the surrounding mountain ranges restrict air movement through and out of the valley. Air pollutants often tend to collect, leading to higher concentrations of emitted pollutants.

3.2 Ambient Air Quality in the Resource Study Area

The CARB maintains ambient air monitoring stations for criteria pollutants throughout California. There are three monitoring stations in the vicinity of the HSR alignment alternatives in Santa Clara County, and one relevant monitoring station in both San Benito and Merced Counties. These stations provide representative ambient criteria pollutant concentrations. The addresses and distances of the stations to the HSR alignment are summarized below.

- San Jose—Jackson Street (156B Jackson Street, San Jose, CA 95110): Approximately 1 mile northeast.
- San Martin—Murphy Avenue (13030 Murphy Ave., San Martin, CA 95046): Approximately 0.25 mile east.
- Gilroy—9th Street (9th and Princeville, Gilroy, CA 95020): Approximately 0.5 mile west.
- Hollister—Fairview Road (1979 Fairview Rd., Hollister, CA 95023): Approximately 9 miles south.
- Merced—S. Coffee Avenue (385 S. Coffee Avenue, Merced, CA 95340): Approximately 18 miles northeast.

Table 2 summarizes the results of ambient monitoring at these stations for the most recent 3 years of available data. Some stations only monitor ozone (O_3), whereas others monitor carbon monoxide (CO), nitrogen dioxide (NO_2), and particulate matter less than or equal to 10 microns in diameter (PM_{10})and PM less than or equal to 2.5 microns in diameter ($PM_{2.5}$).

Between 2016 and 2018, monitored CO, sulfur dioxide (SO_2) NO_2 concentrations did not exceed any federal or state standards at any of the stations that reported monitoring data for these pollutants. However, the state and federal standards for O_3, PM_{10}, and $PM_{2.5}$ were exceeded at one or more stations that reported monitoring data for these pollutants. Using violations of the ambient air quality standards as a proxy for air quality, O_3 and PM conditions tend to be poorest in the vicinity of the eastern portion of the Project in Merced County, with air quality improving westward toward the SFBAAB.

3.3 Resource Study Area Emissions

The CARB maintains an annual emission inventory for each county and air basin in the state. The inventories for Santa Clara, San Benito, and Merced Counties consist of data submitted to CARB

by the local air districts plus estimates for certain source categories, which are provided by CARB staff.

The most recent published inventory data for Santa Clara, San Benito, and Merced Counties is summarized in Table 3. Based on the 2012 air pollutant inventory data, except for San Benito County, mobile source emissions represent most of the volatile organic compounds (VOC), NO_X, and CO emissions. In San Benito County, area sources represent most VOC emissions, and mobile source emissions represent the majority of NO_X and CO. Area sources represent the majority of PM_{10} and $PM_{2.5}$ emissions in all three counties.

[1] An exceedance of a standard is not necessarily a violation because of the regulatory definition of a violation.

[2] National statistics are based on standard conditions data. In addition, national statistics are based on samplers using federal reference or equivalent methods.

[3] State statistics are based on local conditions data, except in the South Coast Air Basin, for which statistics are based on standard conditions data. In addition, state statistics are based on California-approved samplers.

[4] Measurements usually are collected every 6 days.

[5] State criteria for ensuring that data are sufficiently complete for calculating valid annual averages are more stringent than national criteria.

[6] Mathematical estimate of how many days' concentrations would have been measured as higher than the level of the standard had each day been monitored. Values have been rounded.

CAAQS = California ambient air quality standards

mg/m^3 = milligrams per cubic meter

NAAQS = national ambient air quality standards

ppm = parts per million

> = greater than

N/A = not applicable or there was insufficient or no data available to determine the value

4 RELATIONSHIP TO NEPA

The *San Jose to Merced Section Draft EIR/EIS* identifies potential environmental impacts of the Project, both adverse and beneficial, identifies appropriate measures to mitigate adverse impacts, and identifies the agencies' preferred alternative. The EIR/EIS was prepared to comply with both NEPA and CEQA.

The General Conformity regulations establish certain procedural requirements that must be followed when preparing a General Conformity evaluation and are similar, but not identical, to those for conducting an air quality impact analysis under NEPA regulations. NEPA requires that the air quality impacts of the Project's implementation be analyzed and disclosed. For purposes of NEPA, the air quality impacts of the Project were determined by identifying the Project's associated incremental emissions and air pollutant concentrations and comparing them, respectively, to emissions thresholds and to the CAAQS and NAAQS. The air quality impacts of the Project under future Plus Project conditions were also compared in the Draft EIR/EIS to the future No Project conditions for NEPA purposes, and they were compared to existing conditions. The General Conformity Determination process and proposed general findings are discussed in Sections 3.3.4.4, 3.3.6.1, and 3.3.8 of the EIR/EIS.

To appropriately document the identification and offset, where necessary, of the emissions resulting from the Project, the FRA is issuing this draft General Conformity Determination. The Authority has entered into a memorandum of understanding (MOU) with the SJVAPCD that establishes the framework for fully mitigating to net-zero construction emissions of NOx, volatile organic compounds (VOC), PM_{10}, and $PM_{2.5}$. For the SFBAAB and in coordination with the BAAQMD, the Authority will commit to purchase of additional offsets to net all criteria pollutant emissions to levels that are below the General Conformity de minimis level for each calendar year that exceedances occur. Refer to Section 11.2, Compliance with Conformity Requirements, for details on the Authority's commitments.

This Page Intentionally Left Blank

5 PROJECT FEATURES TO REDUCE EMISSIONS

To reduce impacts on the environment, the construction of the Project will include Project features to avoid and minimize impacts on air quality. These Project features will be included in the Mitigation Monitoring and Enforcement Program, which would be issued concurrently with the Final EIR/EIS and ROD for the Project and are enforceable commitments undertaken by the Authority. Construction of the Project is anticipated to occur through contract. The Authority will include all Project features in the construction contract, which would create binding and enforceable commitments to implement.

The Authority would be responsible for implementing and overseeing a mitigation monitoring program so the contractor meets all air quality design features.

Project design features as part of the Project include the following:

AQ-IAMF#1: Fugitive Dust Emissions

During construction, the Contractor shall employ the following measures to minimize and control fugitive dust emissions. The Contractor shall prepare a fugitive dust control plan for each distinct construction segment. At a minimum, the plan shall describe how each measure will be employed and identify an individual responsible for ensuring implementation. At a minimum, the plan shall address the following components unless alternative measures are approved by the applicable air quality management district.

- Cover all vehicle loads transported on public roads to limit visible dust emissions, and maintain at least 6 inches of freeboard space from the top of the container or truck bed.
- Clean all trucks and equipment before exiting the construction site using an appropriate cleaning station that does not allow runoff to leave the site or mud to be carried on tires off the site.
- Water exposed surfaces and unpaved roads at a minimum three times daily with adequate volume to result in wetting the top 1 inch of soil while avoiding overland flow. Rain events may sufficiently wet the top 1 inch of soil to alleviate the need to manually apply water.
- Limit vehicle travel speed on unpaved roads to 15 miles per hour (mph).
- Suspend any dust-generating activities when average wind speed exceeds 25 mph.
- Stabilize all disturbed areas, including storage piles that are not being used on a daily basis for construction purposes, by using water, a chemical stabilizer/suppressant, or hydro mulch or by covering with a tarp or other suitable cover or vegetative ground cover. In areas adjacent to organic farms, the Authority will use nonchemical means of dust suppression.
- Stabilize all on-site unpaved roads and off-site unpaved access roads using water or a chemical stabilizer/suppressant. In areas adjacent to organic farms, the Authority will use nonchemical means of dust suppression.
- Apply water to or presoak all areas where land clearing, grubbing, scraping, excavation, land leveling, grading, cut-and-fill, and demolition activities are carried out.
- For buildings up to six stories tall, wet all exterior surfaces of buildings during demolition.
- Limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at a minimum of once daily, using a vacuum type sweeper.
- After the addition of materials to or the removal of materials from the surface or outdoor storage piles, apply sufficient water or a chemical stabilizer/suppressant.

AQ-IAMF#2: Selection of Coatings

During construction, the contractor will use:

- Low–volatile organic compound (VOC) paint that contains less than 10 percent of VOC contents (VOC, 10%).
- Super-compliant or Clean Air paint that has a lower VOC content than that required by Bay Area Air Quality Management District Regulation 8, Rule 3, Monterey Bay Unified Air Pollution Control District Rule 426, and San Joaquin Valley Unified Air Pollution Control District Rule 4601, when available. If not available, the contractor will document the lack of availability, recommend alternative measure(s) to comply with Regulation 8, Rule 3, Rule 426, and Rule 4601 or disclose absence of measure(s) for full compliance, and obtain concurrence from the Authority.

AQ-IAMF#3: Renewable Diesel

During construction, the Contractor will use renewable diesel fuel to minimize and control exhaust emissions from all heavy-duty diesel-fueled construction diesel equipment and on-road diesel trucks. Renewable diesel must meet the most recent ASTM D975 specification for Ultra Low Sulfur Diesel and have a carbon intensity no greater than 50% of diesel with the lowest carbon intensity among petroleum fuels sold in California. The Contractor will provide the Authority with monthly and annual reports, through the Environmental Mitigation Management and Application (EMMA) system, of renewable diesel purchase records and equipment and vehicle fuel consumption. Exemptions to use traditional diesel can be made where renewable diesel is not available from suppliers within 200 miles of the project site. The construction contract must identify the quantity of traditional diesel purchased and fully document the availability and price of renewable diesel to meet project demand.

AQ-IAMF#4: Reduce Criteria Exhaust Emissions from Construction Equipment

Prior to issuance of construction contracts, the Authority will incorporate the following construction equipment exhaust emissions requirements into the contract specifications:

- All heavy-duty off-road construction diesel equipment used during the construction phase will meet Tier 4 engine requirements.
- A copy of each unit's certified tier specification and any required CARB or air pollution control district operating permit will be made available to the Authority at the time of mobilization of each piece of equipment.
- The contractor will keep a written record (supported by equipment-hour meters where available) of equipment usage during project construction for each piece of equipment.
- The contractor will provide the Authority with monthly reports of equipment operating hours (through the Environmental Mitigation Management and Assessment [EMMA] system) and annual reports documenting compliance.

AQ-IAMF#5: Reduce Criteria Exhaust Emissions from On-Road Construction Equipment

Prior to issuance of construction contracts, the Authority will incorporate the following material-hauling truck fleet mix requirements into the contract specifications:

- All diesel on-road trucks used to haul construction materials, including fill, ballast, rail ties, and steel, shall use a model year 2010 or newer engine.
- The contractor will provide documentation to the Authority of efforts to secure such a fleet mix.
- The contractor will keep a written record of equipment usage during Project construction for each piece of equipment and provide the Authority with monthly reports of vehicle miles traveled (VMT) (through EMMA) and annual reports documenting compliance.

AQ-IAMF#6: Reduce the Potential Impact of Concrete Batch Plants

Prior to construction of any concrete batch plant, the contractor will provide the Authority with a technical memorandum documenting consistency with the Authority's concrete batch plant siting criteria and utilization of typical control measures. Concrete batch plants will be sited at least 1,000 feet from sensitive receptors, including places such as daycare centers, hospitals, senior care facilities, residences, parks, and other areas where people may congregate. The concrete batch plant will implement typical control measures to reduce fugitive dust such as water sprays, enclosures, hoods, curtains, shrouds, movable and telescoping chutes, central dust collection systems, and other suitable technology, to reduce emissions to be equivalent to the USEPA AP-42 controlled emission factors for concrete batch plants. The contractor will provide to the Authority documentation that each batch plant meets this standard during operation.

This Page Intentionally Left Blank

6 REGULATORY PROCEDURES

The General Conformity regulations establish certain procedural requirements that must be followed when preparing a General Conformity evaluation. The procedures required for the General Conformity evaluation are similar, but not identical, to those for conducting an air quality impact analysis pursuant to NEPA. This draft General Conformity Determination is being released for public and agency review pursuant to 40 C.F.R. Section 93.156, and the final General Conformity Determination will be published concurrently with the ROD for the Project.

The Authority identified the appropriate emission estimation techniques and planning assumptions in close consultation with the state entities charged with regulating air pollution in the SFBAAB, NCCAB, and SJVAB.

6.1 Use of Latest Planning Assumptions

The General Conformity regulations require the use of the latest planning assumptions for the area encompassing the Project, derived from the estimates of population, employment, travel, and congestion most recently approved by the area's metropolitan planning organizations (MPO)C.F.R. § 93.159(a)).

The emission estimation techniques, which were slightly different from those used in establishing the applicable SIP emissions budgets, have been approved by the BAAQMD, MBARD, and SJVAPCD. The traffic data used in the air quality analysis are based on the level of ridership as presented in *Connecting and Transforming California, 2016 Business Plan* (2016 Business Plan) (Authority 2016).[6] Further, the traffic data are consistent with the most recent estimates made by the MPOs for traffic volume growth rates, including forecast changes in VMT and vehicle hours traveled. The MPO developed these estimates from their traffic assignment models based on current and future population, employment, and travel and congestion information. These assumptions are consistent with those in the current conformity determinations for the regional transportation plans and transportation improvement programs.

6.2 Use of Latest Emission Estimation Techniques

The General Conformity regulations require the use of the latest and most accurate emission estimation techniques available, unless such techniques are inappropriate (40 C.F.R. § 93.159(b)). Emissions from construction activities were calculated using a combination of emission factors and methodologies from the California Emissions Estimator Model (CalEEMod2, the CARB's EMFAC2017 model, and the USEPA's AP-42 Compilation of Air Pollutant Emission Factors (AP-42) based on Project-specific construction data (e.g., schedule, equipment, truck volumes) provided by the Project design team (Scholz pers. comm.). CalEEMod provides the latest emission factors for construction off-road equipment. It accounts for lower fleet population and growth factors because of the economic recession and updated load factors based on feedback from engine manufacturers. The use of emission rates from CalEEMod reflects the recommendation of the CARB to capture the latest off-road construction assumptions. CalEEMod default load factors (the ratio of average equipment horsepower utilized to maximum equipment horsepower) and useful life parameters were used for emission estimates. CalEEMod default load factors (the ratio of average equipment horsepower utilized to maximum equipment horsepower) and useful life parameters were used for emission estimates.

Construction exhaust emissions from equipment; fugitive dust emissions from earthmoving activities; and emissions from worker trips, deliveries, and material hauling were calculated and

[6] As described in Volume 2, Appendix 3.3-C, Changes to Project Benefits Based on 2018 Business Plan of the EIR/EIS, the Authority Board adopted the 2018 Business Plan on May 15, 2018. The 2018 Business Plan assumes an opening year of 2033 for Phase 1 and presents different ridership forecasts for 2029 and 2040 than were assumed in this EIR/EIS. Under the 2018 Business Plan ridership forecasts, the HSR project would achieve the same benefits described in this section, but they would occur at different times and may be less than those presented in Section 3.3.6, Environmental Consequences. Nonetheless, HSR would ultimately afford a more energy-efficient choice for personal travel that would help alleviate highway congestion, provide greater capacity for goods movement, and reduce criteria pollutant and GHG emissions.

compiled in a spreadsheet tool specific to the Project for each year of construction. Mobile source emission burdens from worker trips and truck trips were calculated using VMT estimates and appropriate emission factors from EMFAC2017. Fugitive dust from re-entrained road dust was calculated using emission factors from USEPA's AP-42, Sections 13.2.1 and 13.2.2. Refer to Chapter 9, Construction Activities Considered, for further detail on the emissions estimation techniques.

6.3 Major Construction-Phase Activities

Project-specific data, including construction equipment lists and the construction schedule, were used for the analysis. Calculations were performed for each year of construction for the Project using default emission factors, as described further in Section 9, Construction Activities Considered.

Major activities were grouped into the following categories:

- Viaduct
- Embankment
- At grade
- Trench
- Tunnel
- Cut and fill

Construction activities associated with each component included demolition, excavation, utilities, roadwork, concrete forming, and other rail work. Each of these activities was considered to evaluate the regional and localized air quality effects during the construction phase. Analysts also quantified emissions from reconductoring approximately 11.1 miles of the existing single-circuit Spring to Llagas and Green Valley to Llagas 115-kilovolt power lines. Refer to Section 9, Construction Activities Considered, for further detail on the construction schedule.

6.4 Emission Scenarios

The General Conformity regulations require that the evaluation reflect certain emission scenarios (40 C.F.R. § 93.159(d)). Specifically, these scenarios generally include the evaluation of direct and indirect emissions from the Project for the following years: (1) for nonattainment areas, the attainment year specified in the SIP, or if the SIP does not specify an attainment year, the latest attainment year possible under the CAA, and for maintenance areas, the farthest year for which emissions are projected in the approved maintenance plan; (2) the year during which the total of direct and indirect emissions for the Project are projected to be the greatest on an annual basis; and (3) any year for which the applicable SIP specifies an emissions budget. Both the operational and construction phases of the Project must be analyzed, and the following applies to the Project:

- Emissions generated during the operational phase of the Project would meet the emission requirements for the years associated with Items 1 and 3 because the emissions generated during the operational phase would be less than those emitted in the No Project scenario. In addition, microscale analyses conducted for the EIR/EIS demonstrate that the operational phase of the Project would not cause or exacerbate a violation of the NAAQS for all applicable pollutants (see Draft EIR/EIS, Section 3.3.6.1).
- Emissions generated during the Project's construction phase, which would include the year with the greatest amount of total direct and indirect emissions (2025, as identified in Item 2), may be subject to General Conformity regulations because they would increase regional emission rates and, as such, have the potential to cause or exacerbate an exceedance of the NAAQS. Therefore, analyses were conducted to estimate the amounts of emissions that would be generated during the construction phase (for comparison with the General Conformity applicability rates) and the potential impacts of these emissions on local air quality levels. Emissions generated at the construction sites (e.g., tailpipe emissions from the on-site heavy-duty diesel equipment and fugitive dust emissions generated by vehicles traveling within the construction sites) and on the area's roadways by vehicles traveling to and from

these sites (by vehicles transporting materials and the workers traveling to and from work) were considered.

- Air quality dispersion modeling would be required for this conformity analysis to estimate the Project's localized impacts on PM concentrations if the annual emissions of the pollutants generated during construction were to exceed the General Conformity *de minimis* thresholds.

Annual emissions were estimated for each year of the Project's construction period. These emissions, which are the maximum values for the Project, are described in more detail in Section 10, Estimated Emission Rates and Comparison to *de minimis* Thresholds, of this report.

This Page Intentionally Left Blank

7 APPLICABILITY ANALYSIS

The first step in a General Conformity evaluation is an analysis of whether the requirements apply to a proposed federal action in a nonattainment or a maintenance area. Unless exempted by the regulations or otherwise presumed to conform, a Federal action requires a General Conformity Determination for each pollutant where the total of direct and indirect emissions caused by the Project would equal or exceed an annual *de minimis* emission rate.

7.1 Attainment Status of Resource Study Area

The USEPA designates each county (or portions of counties) within California as attainment, maintenance, or nonattainment based on the area's ability to maintain ambient air concentrations below the air quality standards. Areas are designated as attainment if ambient air concentrations of a criteria pollutant are below the ambient standards. Areas are designated as nonattainment if ambient air concentrations are above the ambient standards. Areas previously designated as nonattainment that subsequently demonstrated compliance with the standards are designated as maintenance. Table 4 summarizes the attainment status of the SFBAAB, NCCAB, and SJVAB with regard to the NAAQS and CAAQS.

Table 4 Federal Attainment Status of the SFBAAB, NCCAB, and SJVAB

Pollutant	SFBAAB	NCCAB	SJVAB
O_3	Marginal Nonattainment	Attainment	Extreme Nonattainment
PM_{10}	Attainment	Attainment	Serious Maintenance
$PM_{2.5}$	Moderate Nonattainment	Attainment	Serious/Moderate Nonattainment[1]
CO	Attainment	Attainment	Attainment
NO_2	Attainment	Attainment	Attainment
SO_2	Attainment	Attainment	Attainment

Source: USEPA 2018
CO = carbon monoxide
NCCAB = North Central Coast Air Basin
NO_2 = nitrogen dioxide
O_3 = ozone
$PM_{2.5}$ = particulate matter smaller than or equal to 2.5 microns in diameter
PM_{10} = particulate matter smaller than or equal to 10 microns in diameter
SFBAAB = San Francisco Bay Area Air Basin
SJVAB = San Joaquin Valley Air Basin
SO_2 = sulfur dioxide
[1] The SJVAB is serious nonattainment for the 2006 $PM_{2.5}$ standard and moderate nonattainment for the 2012 $PM_{2.5}$ standard.

Under federal designations, the RSA is currently designated as extreme and marginal nonattainment for 8-hour O_3[7] in the SJVAB and SFBAAB, respectively; moderate/serious nonattainment for $PM_{2.5}$ in the SFBAAB and SJVAB; and maintenance for PM_{10} in the SJVAB. As such, the FRA is required to demonstrate project-level compliance with the General Conformity Rule for NO_X and VOCs (O_3 precursors), $PM_{2.5}$, PM_{10}, and SO_2 ($PM_{2.5}$ precursor[8]), if Project-related emissions of these pollutants in the SFBAAB or SJVAB would exceed the General Conformity *de minimis* thresholds.

[7] It should be noted that because O_3 is a secondary pollutant (i.e., it is not emitted directly into the atmosphere, but is formed in the atmosphere from the photochemical reactions of VOCs and NO_X in the presence of sunlight), its *de minimis* threshold is based on primary emissions of its precursor pollutants, NO_X and VOCs. If the net emissions of either NO_X or VOCs exceeds the *de minimis* applicability thresholds (USEPA 1994), the Project is subject to a general conformity evaluation for O_3.

[8] Ammonia is also a precursor to $PM_{2.5}$. However, neither construction nor operation of the Project would result in material emissions of ammonia.

As shown in Table 4, the portion of the RSA in the NCCAB is in attainment for all criteria pollutants. As outlined in Section III.A of the General Conformity Rule, “only actions which cause emissions in designated nonattainment and maintenance areas are subject to the regulations.” As such, a General Conformity analysis is not required for the portion of the Project within the NCCAB. There are no applicable *de minimis* thresholds, and no further discussion of Project activities in the NCCAB is provided in this General Conformity Determination.

7.2 Exemptions from General Conformity Requirements

As noted previously, the General Conformity requirements apply to a federal action if the net Project emissions equal or exceed certain *de minimis* emission rates. The only exceptions to this applicability criterion are if the activity is on the federal agency’s presumed-to-conform list (40 C.F.R. § 93.153(f)), meets the narrow exemption for federal actions in response to an emergency or disaster (40 C.F.R. § 93.153(e)), or is one of the following topical exemptions:

- Actions that would result in no emissions increase or an increase in emissions that is clearly below the *de minimis* levels (40 C.F.R. § 93.153(c)(2)). Examples include administrative actions and routine maintenance and repair.
- Actions where the emissions are not reasonably foreseeable (40 C.F.R. § 93.153(c)(3))
- Actions which implement a decision to conduct or carry out a conforming program (40 C.F.R. § 93.153 (c)(4))
- Actions which include major new or modified sources requiring a permit under the New Source Review program (40 C.F.R. § 93.153(d)(1))
- Actions in response to emergencies or natural disasters (40 C.F.R. § 93.153(d)(2))
- Actions which include air quality research not harming the environment (40 C.F.R. § 93.153(d)(3))
- Actions which include modifications to existing sources to enable compliance with applicable environmental requirements (40 C.F.R. § 93.153(d)(4))
- Actions which include emissions from remedial measures carried out under the Comprehensive Environmental Response, Compensation and Liability Act that comply with other applicable requirements (40 C.F.R. § 93.153(d)(5)).

However, the Project does not meet any of the exemption categories described above. In addition, the FRA has not established a presumed-to-conform list of activities at the time of this evaluation, and the Project does not meet the requirements of 40 C.F.R. Section 93.153(e).

7.3 Applicability for Project

After determining that the Project is not otherwise exempt, the applicability of the General Conformity requirements to the Project is evaluated by comparing the total of direct and indirect emissions for the calendar year of greatest emissions to the General Conformity *de minimis* thresholds. Where the total of direct and indirect emissions attributable to the Project is found to be below the *de minimis* emission rates for a pollutant, that pollutant is excluded from General Conformity requirements, and no further analysis is required. However, when the emissions of an applicable pollutant are at or above a *de minimis* threshold, that pollutant must undergo a General Conformity evaluation.

7.4 *De Minimis* Emission Rates

The General Conformity requirements would apply to the Project for each pollutant for which the total of direct and indirect emissions caused by the Project equal or exceed the *de minimis* emission rates shown in Table 5. These emission rates are expressed in units of tons per year (tpy) for the Project in each air basin for the calendar year. The applicable threshold levels for the pollutants for which General Conformity is required in the RSA are shown in Table 5.

Table 5 *De Minimis* Rates for Determining Applicability of General Conformity Requirements to Federal Actions

Air Basin	Annual Air Pollutant Emissions in Tons per Year					
	VOC	NO_X	CO	PM_{10}	$PM_{2.5}$	SO_2
San Francisco Bay Area Air Basin[1]	100	100	None	None	100	100
San Joaquin Valley Air Basin[2]	10	10	None	100	70	70
North Central Coast Air Basin[3]	None	None	None	None	None	None

Source: 40 C.F.R. Section 93.153
CO = carbon monoxide
NO_X = oxides of nitrogen
O_3 = ozone
$PM_{2.5}$ = particulate matter 2.5 microns in diameter or less
PM_{10} = particulate matter 10 microns in diameter or less
VOC = violate organic compounds
SO_2 = sulfur dioxide
[1] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the RSA in the SFBAAB. The RSA is considered a marginal nonattainment area for the O_3 NAAQS and a moderate nonattainment area for the $PM_{2.5}$ NAAQS. Although the RSA is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used.
[2] The General Conformity *de minimis* thresholds for criteria pollutants are based on the federal attainment status of the RSA in the SJVAB. The RSA is considered an extreme nonattainment area for the O_3 NAAQS, a serious/moderate nonattainment area for the $PM_{2.5}$ NAAQS, and a serious maintenance area for the PM_{10} NAAQS. Although the RSA is in attainment for SO_2, because SO_2 is a precursor for $PM_{2.5}$, the $PM_{2.5}$ General Conformity *de minimis* thresholds are used. For $PM_{2.5}$ and SO_2, the *de minimis* threshold for projects located in serious nonattainment areas are used because this threshold is lower than the 100 tons per year threshold for projects exclusively in moderate nonattainment areas.
[3] The NCCAB is in attainment for all criteria pollutants (see Table 4).

This Page Intentionally Left Blank

8 CONSTRUCTION ACTIVITIES CONSIDERED

As shown in Section 3.3.6.1 of the Draft EIR/EIS, the results of the regional analyses conducted for the Project demonstrate that emissions generated during the operational phase would be less than those emitted in the No Project and existing conditions scenarios and that the microscale analyses demonstrate that the Project would not cause or exacerbate a violation of the NAAQS for these pollutants. As such, no further analysis of the operational period emissions is necessary for this General Conformity Determination. This section focuses on the emissions generated from the construction period emissions for the Project.

The analysis conducted for the EIR/EIS to estimate potential air quality impacts caused by on-site (e.g., demolition activities, construction equipment operations, and truck movements) and off-site (e.g., motor vehicle traffic effects because of truck trips) construction-phase activities included the following:

- Estimation of emissions generated by the construction activities (e.g., deconstruction, concrete and steel construction), including fugitive dust emissions and emissions released from diesel-powered equipment and trucks based on the hours of operation of each piece of equipment[9]
- Identification of heavily traveled truck routes to estimate the cumulative effects of on-site construction activity emissions and off-site traffic emissions
- An on-site dispersion modeling analysis of the major construction areas
- An off-site dispersion modeling analysis of the roadway intersections and interchanges adjacent to the construction areas, using traffic data that include construction-related vehicles and background traffic
- A comparison of the on-site and off-site modeling results to the applicable NAAQS for the applicable pollutants

Emission rates for these activities were estimated based on the following:

- The number of hours per day and duration of each construction activity
- The number and type of construction equipment to be used
- HP and utilization rates (hours per day) for each piece of equipment
- The quantities of construction/demolition material produced and removed from each site
- The number of truck trips needed to remove construction and demolition material and to bring the supply materials to each site

The following is a discussion of the construction analysis methodology. A full list of assumptions can be found in the EIR/EIS, Appendix C to the *San Jose to Merced Project Section Air Quality and Greenhouse Gases Technical Report* (Authority and FRA 2019).

8.1 Models and Methods for Emissions Modeling

Construction of the Project would generate emissions of VOC, NO_X, CO, sulfur oxide (SO_X) PM_{10}, and $PM_{2.5}$. Emissions would originate from off-road equipment exhaust, employee and haul truck vehicle exhaust (on-road vehicles) site grading and earth movement, concrete batching, demolition, paving, architectural coating, and helicopters (for reconductoring work). These emissions would be temporary (i.e., limited to the construction period) and would cease when construction activities are complete.

[9] It is possible changes in VMT, speeds, or idle times resulting from traffic detours during construction could result in additional emissions. However, it is unknown to what extent motorists will change their driving patterns as a result of traffic detours and impediments, and, as such, it would be speculative to quantify the impact of temporary roadway restrictions on criteria pollutant emissions.

Combustion exhaust, fugitive dust (PM_{10} and $PM_{2.5}$), and fugitive off-gassing (VOCs) were estimated using a combination of emission factors and methodologies from CalEEMod, version 2016.3.2; the CARB's EMFAC2017 model, and the USEPA's AP-42 Compilation of Air Pollutant Emission Factors based on Project-specific construction data (e.g., schedule, equipment, truck volumes) provided by the Project design team (Scholz pers. comm.).

- **Off-road equipment**—Emission factors for off-road construction equipment (e.g., loaders, graders, bulldozers) were obtained from the CalEEMod (version 2016.3.2) User's Guide appendix, which provides values per unit of activity (in grams per horsepower-hour) by calendar year (Trinity Consultants 2016. Analysts estimated criteria pollutants by multiplying the CalEEMod emission factors by the equipment inventory provided by the Project engineering team (Scholz pers. comm.).
- **On-road vehicles**—On-road vehicles (e.g., pickup trucks, flatbed trucks) would be required for material and equipment hauling, on-site crew and material movement, and employee commuting. The analysis estimated exhaust emissions from on-road vehicles using the EMFAC2017 emissions model and activity data (miles traveled per day) provided by the Project engineering team (Scholz pers. comm.). Emission factors for haul trucks are based on aggregated-speed emission rates for EMFAC's T7 Single vehicle category. Factors for on-site dump, water, boom, and concrete trucks were based on 5 mph emission rates for the T6 Heavy category. Factors for employee commute vehicles were based on a weighted average for all vehicle speeds for EMFAC's light-duty automobile/light-duty truck vehicle categories. CARB's (2019) Safer Affordable Fuel-Efficient [SAFE] Vehicles Rule adjustment factors were applied to the emission factors for gasoline-powered vehicles. Fugitive re-entrained road dust emissions were estimated using the USEPA's *Compilation of Air Pollutant Emission Factors* (AP-42), Sections 13.2.1 and 13.2.2 (USEPA 2006, 2011).
- **Site grading and earth movement**—Fugitive dust emissions from earth movement (e.g., site grading, bulldozing, and truck loading) were quantified using emission factors from CalEEMod and USEPA (1998) AP-42cut-and-fill material were provided by the Project engineering team (Scholz pers. comm.).
- **Concrete batching**—Fugitive dust emissions from concrete batching at the three new temporary batch plants were quantified using emission factors from BAAQMD's (2016) Permit Handbook and USEPA's AP-42. Daily and annual batch quantities (cubic yards) were provided by the Project engineering team (Scholz pers. comm
- **Demolition**—Fugitive dust emissions from building demolition were based on the anticipated amount of square feet to be demolished and calculation method from the CalEEMod User's Guide (Trinity Consultants 2016).
- **Paving**—Fugitive VOC emissions associated with paving were calculated using activity data (e.g., square feet paved) provided by the Project engineer and the CalEEMod default emission factor of 2.62 pounds of VOC per acre paved (Scholz pers. comm.).
- **Architectural coating**—Fugitive VOC emissions associated with architectural coatings of the stations were calculated using activity data (e.g., square feet coated) provided by the Project engineering team and methods contained in the CalEEMod User's Guide (Scholz pers. comm.). Emissions calculations assume a VOC content of 150 grams per liter (g/L), consistent with BAAQMD's Regulation 8, Rule 3, Section 301.
- **Helicopters**—Helicopters would be required for the reconductoring work. Exhaust emissions were calculated using emission factors and assumptions derived from a review of guidance manuals published by USEPA (1978) The Climate Registry (2018).

8.2 Ballast and Subballast Hauling

Ballast and subballast materials could be transported from multiple quarry locations throughout Northern California and the Central Valley. Analysts estimated emissions from ballast and subballast material hauling by trucks and locomotives based on the travel distances and

transportation method (by rail or by truck) from the locations where ballast materials would be available. Analysts used heavy-duty truck emission factors (T7 Single) from EMFAC2017 to estimate emissions from haul trucks and rail emission factors from the USEPA (2009 to estimate the locomotive emissions. to estimate the locomotive emissions.

Analysts identified up to 11 potential quarries that could provide ballast material. All quarries are within the SFBAAB, MBARD, and SJVAPCD, with the furthest quarry located 37 rail miles and 89 highway miles from the Project footprint. Ballast and subballast quantities for the Project were provided by the Project engineering team and distributed equally among the identified quarries (Scholz pers. comm.). Scenario 1 assumed ballast and subballast would be hauled to the Project footprint using a combination of trucks and locomotives, and Scenario 2 assumed ballast and subballast would be hauled to the Project footprint using only trucks.

8.3 Annual Emissions Estimates

As discussed in Section 7.3, Major Construction-Phase Activities, up to six construction activities (viaduct, embankment, at grade, trench, tunnel, and large cut and fill) would be constructed, depending on the subsection and alternative. The analysis assumes that each component would be constructed over multiple phases between 2022 and 2028.[10]

8.4 Emissions by Air Basin

Activities occurring within the SFBAAB and SJVAB were quantified and analyzed separately to compare emissions to appropriate *de minimis* thresholds. Emissions generated by construction of subsections that would occur exclusively within one air basin (e.g., San Jose Diridon Station Approach in the SFBAAB) were wholly assigned to that air basin. Emissions estimates for alternatives that span more than one air district were apportioned based on the location of construction activity. For example, construction of the Pacheco Pass Subsection would occur in both the SFBAAB and SJVAB. Accordingly, the emissions estimates were apportioned to the SFBAAB and SJVAB based on the number of rail miles constructed within each air basin. Table 6 summarizes the location of each subsection and the air basin scaling factors used in the analysis, as appropriate. All reconductoring work would occur in the SFBAAB.

[10] Construction is expected to take place later than the dates assumed in the air quality analysis. The construction emissions estimates are therefore conservative, as future emissions rates will be lower due to the implementation of cleaner and newer equipment.

Table 6 Track Miles and Construction Scaling Factors by Air Basin

Subsection	Alternative 1		Alternative 2		Alternative 3		Alternative 4	
	SFBAAB	SJVAB	SFBAAB	SJVAB	SFBAAB	SJVAB	SFBAAB	SJVAB
Constructed Rail Miles								
San Jose Diridon Station Approach	3	0	3	0	3	0	3	0
Monterey Corridor	4	0	4	0	4	0	4	0
Morgan Hill and Gilroy	14	0	14	0	13	0	14	0
Pacheco Pass	5	7	5	7	5	7	5	7
San Joaquin Valley	0	9	0	9	0	9	0	9

[1] The remaining 13–15 percent of track miles would be constructed in the NCCAB. However, as discussed in Section 8.1, Attainment Status of Resource Study Area, the portion of the RSA in the NCAAB is in attainment for all criteria pollutants. As such, a general conformity analysis is not required, and no further discussion of Project activities in the NCCAB is provided in this General Conformity Determination.

8.5 Project Design Features

The Authority has developed IAMFs to reduce air quality effects. Because IAMFs are included as part of the Project design, they are not considered mitigation, and are included as part of the Project construction emissions estimate. Specifically, the following emissions benefits achieved by AQ-IAMF#1 through AQ-IAMF#6 were assumed in the modeling. estimate. Specifically, the following emissions benefits achieved by AQ-IAMF#1 through AQ-IAMF#6 were assumed in the modeling.

- Fugitive dust reductions from earthmoving best management practices (AQ-IAMF#1) (Countess Environmental 2006).
  - PM from ground disturbance (i.e., scraping and grading activities), 75 percent (BAAQMD 2017a)
  - PM from unpaved vehicle travel (i.e., re-entrained road dust), 75 percent[11]
  - PM from demolition, 36 percent (Countess Environmental 2006)
- VOC reductions (93 percent) from application of architectural coatings (AQ-IAMF#2).[12]
- Criteria pollutant and greenhouse gas (GHG) Lovegrove and Tadross 2017))
  - CO, 10 percent (Tier 2 tunneling equipment)
  - NO_X, 10 percent (Tier 2 tunneling equipment)
  - PM, 30 percent (all engines)
- Criteria pollutant and GHG reductions from use of Tier 4 off-road engines (AQ-IAMF#4). Emissions reductions vary by pollutant and equipment type. Emissions were modeled using Tier 4 emission rates from CalEEMod.
- Criteria pollutant and GHG reductions from use of model year 2010 or newer on-road engines in heavy-duty, diesel powered trucks (AQ-IAMF#5). Emissions reductions vary by pollutant, analysis year, and air basin. Emissions were modeled using emission rates for model year 2010 or newer engines derived from the CARB's EMFAC2017 model. The emissions rates for model year 2010 and newer engines reflect implementation of EPA's December 2000 Control of Air Pollution from New Motor Vehicles: Heavy-Duty Engine and Vehicle Standards and Highway Diesel Fuel Sulfur Control Requirements.
- Fugitive dust reductions from implementation of typical control measures at new concrete batch plants, such as water sprays, enclosures, and hoods (AQ-IAMF#6). Emissions were modeled using USEPA AP-42 controlled emission factors for concrete batch plants

[11] Among other controls, this IAMF requires watering unpaved roads three times daily and limiting vehicle speeds. The 75 percent efficacy is based on a 55 percent reduction for watering and a 44 percent reduction for vehicle speed limits (1-(.55*.44)) = 0.75% (Countess Environmental 2006).

[12] Assumes an uncontrolled VOC content of 150 g/L per BAAQMD Regulation 8, Rule 3, Section 301 and a controlled VOC content of 10 g/L per AQ-IAMF#2.

9 ESTIMATED EMISSION RATES AND COMPARISON TO *DE MINIMIS* THRESHOLDS

Total annual estimated emissions generated within the SFBAAB and SJVAB during the construction period, as presented in the EIR/EIS, are provided in Tables 7 and 8. These values are the peak on-site emissions during each analysis year, plus maximum annual off-site emissions. The modeling accounts for implementation of AQ-IAMF#1 through AQ-IAMF#6 and reflects the impact of the SAFE Vehicle Rule (CARB 2019Emissions for each Project alternative, including the Preferred Alternative 4, are presented and analyzed in this General Conformity Determination.

As shown in the tables, annual construction emissions of all Project alternatives would exceed the General Conformity *de minimis* threshold in the SJVAB for NO_X for all years of construction between 2022 and 2028. NOx emissions would also exceed the General Conformity *de minimis* threshold in the SFBAAB in 2024 under Alternatives 1 and 3, and between 2023 and 2025 under Alternatives 2 and 4. All other pollutants would be below applicable *de minimis* thresholds.

[4] Construction activities and associated emissions are the same among the four alternatives in the SJVAB.

This Page Intentionally Left Blank

10 REGIONAL EFFECTS

As shown in Section 3.3.6.1 of the Draft EIR/EIS, the total regional emissions for all applicable pollutants are lower during the operations phase of the Project than under No Project conditions (and would therefore not exceed the *de minimis* emission thresholds). As such, only emissions generated during the construction phase were compared to the conformity threshold levels to determine conformity compliance. As shown in Tables 7 and 8, construction-phase emissions, compared to the General Conformity applicability rates, are as follows:

- Annual estimated NO_X emissions in the SJVAB are greater than the applicability rate of 10 tpy for all years of construction between 2022 and 2028 for all Project alternatives with implementation of IAMFs.
- Annual estimated NO_X emissions in the SFBAAB are greater than the applicability rate of 100 tpy in 2024 under Alternatives 1 and 3 and for all years of construction between 2023 and 2025 under Alternatives 2 and 4 with implementation of IAMFs.
- Annual estimated VOC, CO, SO_2, PM_{10}, and $PM_{2.5}$ emissions are less than the applicability rates in the SFBAAB and SJVAB with implementation of IAMFs.

Therefore, a General Conformity Determination is required for the Project for NO_X for the years during construction when the emissions would exceed the *de minimis* thresholds in the SFBAAB and SJVAB and do not meet any of the exceptions cited in 40 C.F.R. Section 93.154(c).

This Page Intentionally Left Blank

11 GENERAL CONFORMITY EVALUATION

For federal actions subject to a General Conformity evaluation, the regulations delineate several ways an agency can demonstrate conformity (40 C.F.R. § 93.158). This section summarizes the findings that were used to make the determination for the Project.

11.1 Conformity Requirements of Project

Based on the results shown in Tables 7 and 8, conformity determinations are required for construction-phase emissions for NO_X because annual estimated emissions are greater than the applicability rates of 100 tpy in the SFBAAB and 10 tpy in the SJVAB.

11.2 Compliance with Conformity Requirements

NO_X (a precursor to O_3) emissions caused by the construction of the Project would not result in an increase in regional NO_X emissions in the SFBAAB or SJVAB because exceedances would be mitigated by offsets. This would be achieved by additional on-site controls and offsetting remaining NO_X emissions generated by the construction of the Project in a manner consistent with the General Conformity regulations.

The requirements for offsets (as described below) would be implemented as part of the Project and will be included in the mitigation measures in the Final EIR/EIS. Any required offsets are anticipated to be accomplished by entering into an agreement with BAAQMD and project-level VERA with the SJVAPCD. The requirement for the VERA (as described below) would be implemented as part of the project and will be included in the mitigation measures in the Final EIR/EIS:

AQ-MM#1: Implement Additional On-Site Emissions Controls to Reduce Fugitive Dust

During construction, the contractor shall employ the following measures to minimize and control fugitive dust emissions:

- Where feasible, install wind breaks (e.g., dust curtains, plastic tarps, solid fencing) on the average dominant windward side(s) of station construction areas. For purposes of implementation, chain-link fencing with added landscape mesh fabric adequately qualifies as solid fencing.
- Post a publicly visible sign with the telephone number and person to contact at the Authority regarding dust complaints. This person shall respond and take corrective action within 48 hours. The phone number for the local air district shall also be visible to ensure compliance with applicable regulations.

AQ-MM#2: Construction Emissions Reductions – Requirements for use of Zero Emission (ZE) and/or Near Zero Emission (NZE) Vehicles and off-road equipment

This mitigation measure will reduce the impact of construction emissions from Project

This mitigation measure will reduce the impact of construction emissions from project-related on-road vehicles and off-road equipment.

The Authority and all project construction contractors shall require that a minimum of 25 percent, with a goal of 100 percent, of all light-duty on-road vehicles (e.g., passenger cars, light-duty trucks) associated with the project (e.g., on-site vehicles, contractor vehicles) use ZE or NZE technology.

The Authority and all project construction contractors shall have the goal that a minimum of 25 percent of all heavy-duty on-road vehicles (e.g., for hauling, material delivery and soil import/export) associated with the project use ZE or NZE technology.

The Authority and all project construction contractors shall have the goal that a minimum of 10 percent of off-road construction equipment use ZE or NZE vehicles.

If local or state regulations mandate a faster transition to using ZE and/or NZE vehicles at the time of construction, the more stringent regulations will be applied. For example, Executive Order (EO) N-79-20, issued by California Governor Newsom September 23, 2020, currently states the following:

- Light duty and passenger car sales be 100 percent ZE vehicles by 2035
- Full transition to ZE short haul/drayage trucks by 2035
- Full transition to ZE heavy-duty long-haul trucks, where feasible, by 2045
- Full transition to ZE off-road equipment by 2035, where feasible.

The project will have a goal of surpassing the requirements of these or other future regulations as a mitigation measure.

AQ-MM#3: Offset Project Construction Emissions in the San Francisco Bay Area Air Basin

Prior to issuance of construction contracts, the Authority will conduct an air quality analysis that evaluates the conditions that exist at that time. If the analysis determines that there will be exceedances of the VOC or NOx thresholds, even after the application of the mitigation in AQ-MM#2, the Authority will enter into an agreement with BAAQMD to reduce VOC and NO_X to the required levels by acquiring offsets. The required levels in the SFBAAB are as follows:

1. For emissions in excess of the General Conformity *de minimis* thresholds (NO_X): net zero.
2. For emissions not in excess of *de minimis* thresholds but above the BAAQMD's daily emission thresholds (VOC and NO_X): below the appropriate CEQA threshold levels.

The mitigation offset fee amount will be determined at the time of mitigation to fund one or more emissions reduction projects within the SFBAAB. The offset fee will be determined by the Authority and BAAQMD based on the type of projects that present appropriate emission reduction opportunities. These funds may be spent to reduce either VOC or NO_X emissions ("O_3 precursors"). Documentation of payment will be provided to the Authority or its designated representative.

The agreement will include details regarding the annual calculation of required offsets the Authority must achieve, funds to be paid, administrative fee, and the timing of the emissions reductions projects. Acceptance of this fee by BAAQMD will serve as an acknowledgment and commitment by BAAQMD to: (1) implement an emissions reduction project(s) within a timeframe to be determined based on the type of project(s) selected after receipt of the mitigation fee designed to achieve the emission reduction objectives; and (2) provide documentation to the Authority or its designated representative describing the project(s) funded by the mitigation fee, including the amount of emissions reduced (tons per year) in the SFBAAB from the emissions reduction project(s). To qualify under this mitigation measure, the specific emissions reduction project(s) must result in emission reductions in the SFBAAB that are real, surplus, quantifiable, enforceable, and will not otherwise be achieved through compliance with existing regulatory requirements or any other legal requirement. Pursuant to 40 C.F.R. Section 93.163(a), the necessary reductions must be achieved (contracted and delivered) by the applicable year in question. Funding will need to be received by BAAQMD prior to contracting with participants and should allow enough time to receive and process applications to fund and implement off-site reduction projects prior to commencement of project activities being reduced. This will roughly equate to 1 year prior to the required mitigation; additional lead time may be necessary depending on the level of off-site emission reductions required for a specific year.

This mitigation measure will be effective in offsetting emissions generated during project construction through the funding of emission-reduction projects. It is BAAQMD's experience that emissions offsets are feasible mitigation that effectively achieves actual emission reductions (Kirk 2018).

The implementation of this mitigation measure will not be expected to affect air quality in the BAAQMD because purchasing emissions offsets will not result in any physical change to the environment, and therefore will not result in other secondary environmental impacts. In addition to

VOC and NO_X, the implementation of emission-reduction projects could result in reductions of other criteria pollutants and/or GHGs. However, this will be a secondary effect of this mitigation measure and is not a required outcome to mitigate any impacts of the project.

AQ-MM#4: Offset Project Construction Emissions in the San Joaquin Valley Air Basin

On June 19, 2014, the SJVAPCD and the Authority entered an MOU that establishes the framework for fully mitigating to net-zero construction emissions of NOx, VOC, PM_{10}, and $PM_{2.5}$ from the entire HSR project within the SJVAB (Authority and SJVUAPCD 2014). Emissions generated by construction of the portion of the project within the SJVAB are subject to this MOU and, therefore, must be offset to net zero. Pursuant to the MOU, the Authority and the SJVAPCD will enter into a Voluntary Emissions Reduction Agreement (VERA) to cover the portion of the project approved and funded for construction within the SJVAB. The project-level VERA must be executed prior to commencement of construction and the mitigation fees and offsets delivered and achieved according to the requirements of the VERA and MOU.

This mitigation measure will be effective in offsetting emissions generated during construction of the project through the funding of emission-reduction projects. It is SJVAPCD's experience that implementation of a VERA is feasible mitigation that effectively achieves actual emission reductions. Based on the performance of current incentive programs and reasonably foreseeable future growth, the SJVAPCD has confirmed that enough emissions reduction credits will be available to offset emissions generated by the project for all years in excess of the SJVAPCD's thresholds and the General Conformity *de minimis* threshold (Authority and SJVUAPCD 2014).

The implementation of this mitigation measure will not be expected to affect air quality in the SJVAPCD because purchasing emissions offsets will not result in any physical change to the environment, and therefore will not result in other secondary environmental impacts. In addition to NO_X and PM_{10}, the implementation of emission-reduction projects could result in reductions of other criteria pollutants, GHGs, or both. However, this will be a secondary effect of this mitigation measure and is not a required outcome to mitigate any impacts of the project.

11.3 Consistency with Requirements and Milestones in Applicable SIP

The General Conformity regulations state that notwithstanding the other requirements of the rule, a federal action may not be determined to conform unless the total of direct and indirect emissions from the federal action is in compliance or consistent with all relevant requirements and milestones in the applicable SIP (40 C.F.R. § 93.158(c)). This includes, but is not limited to, such issues as reasonable further progress schedules, assumptions specified in the attainment or maintenance demonstration, prohibitions, numerical emission limits, and work practice standards. This section briefly addresses how the construction emissions for the Project were assessed for SIP consistency for this evaluation.

11.3.1 Applicable Requirements from U.S. Environmental Protection Agency

The USEPA promulgates requirements to support the goals of the CAA with respect to the NAAQS. Typically, these requirements take the form of rules regulating emissions from significant new sources, including emission standards for major stationary point sources and classes of mobile sources, as well as permitting requirements for new major stationary point sources. Since states have the primary responsibility for implementation and enforcement of requirements under the CAA and can impose stricter limitations than the USEPA, the USEPA requirements often serve as guidance to the states in formulating their air quality management strategies.

11.3.2 Applicable Requirements from California Air Resources Board

In California, to support the attainment and maintenance of the NAAQS, the CARB is primarily responsible for regulating emissions from mobile sources. In fact, the USEPA has delegated authority to the CARB to establish emission standards for on-road and some non-road vehicles separate from the USEPA vehicle emission standards, although the CARB is preempted by the CAA from regulating emissions from many non-road mobile sources, including marine craft. Emission standards for preempted equipment can only be set by the USEPA.

11.3.3 Applicable Requirements from Bay Area Air Quality Management District and San Joaquin Valley Air Pollution Control District

To support the attainment and maintenance of the NAAQS in the SFBAAB and SJVAB, the BAAQMD and SJVAPCD have primarily been responsible for regulating emissions from stationary sources. As noted above, the BAAQMD and SJVAPCD develop and update their air quality management plans regularly to support the California SIP. While the plans contain rules and regulations geared to attain and maintain the NAAQS, these rules and regulations also have the much more difficult goal of attaining and maintaining the CAAQS.

11.3.4 Consistency with Applicable Requirements for the California High-Speed Rail Authority

The Authority already complies with, and will continue to comply with, a myriad of rules and regulations implemented and enforced by federal, state, regional, and local agencies to protect and enhance ambient air quality in the SFBAAB and SJVAB.

In particular, because of the long persistence of challenges to attain the ambient air quality standards in the SFBAAB and SJVAB, the rules and regulations promulgated by the CARB, BAAQMD, and SJVAPCD are among the most stringent in the U.S.

The Authority will continue to comply with all existing applicable air quality regulatory requirements for activities over which it has direct control and would meet in a timely manner all regulatory requirements that become applicable in the future.

These are appropriate USEPA, CARB, BAAQMD, and SJVAPCD rules which are standard practices and best management practices for construction in the BAAQMD and SJVAPCD, including control of emissions and exhaust:

- **BAAQMD Regulation 2, Rule 2 (New Source Review)**—This rule contains requirements for Best Available Control Technology and emission offsets.
- **BAAQMD Regulation 2, Rule 5 (New Source Review of Toxic Air Contaminates)**—This rule outlines guidance for evaluating TAC emissions and their potential health risks.
- **BAAQMD Regulation 6, Rule 1 (Particulate Matter)**—This rule restricts emissions of PM darker than No. 1 on the Ringlemann Chart to less than 3 minutes in any 1 hour.
- **BAAQMD Regulation 6, Rule 6 (Prohibition of Trackout)**—This rule limits the quantity of PM in the atmosphere through control of trackout of solid materials onto paved public roads outside the boundaries of Large Bulk Material Sites, Large Construction Sites, and Large Disturbed Surface sites including landfills.
- **BAAQMD Regulation 7 (Odorous Substances)**—This regulation establishes general odor limitations on odorous substances and specific emission limitations on certain odorous compounds.
- **BAAQMD Regulation 8, Rule 3 (Architectural Coatings)**—This rule limits the quantity of VOC in architectural coatings.
- **BAAQMD Regulation 9, Rule 6 (Nitrogen Oxides Emission from Natural Gas–Fired Boilers and Water Heaters)**—This rule limits emissions of NO_X generated by natural gas–fired boilers.
- **BAAQMD Regulation 9, Rule 8 (Stationary Internal Combustion Engines)**—This rule limits emissions of NO_X and CO from stationary internal combustion engines of more than 50 horsepower.
- **BAAQMD Regulation 11, Rule 2 (Asbestos Demolition, Renovation, and Manufacturing)**—This rule controls emissions of asbestos to the atmosphere during demolition, renovation, milling, and manufacturing and establishes appropriate waste disposal procedures.

- **SJVAPCD Rule 2010 (Permits Required)—**This rule requires any person constructing, altering, replacing or operating any source operation which emits, may emit, or may reduce emissions to obtain an Authority to Construct or a Permit to Operate.
- **SJVAPCD Rule 2201 (New and Modified Stationary Source Review)**—This rule requires that sources not increase emissions above the specified thresholds.
- **SJVAPCD Rule 2280 (Portable Equipment Registration)**—This rule requires portable equipment used at project sites for less than 6 consecutive months be registered with the SJVAPCD.
- **SJVAPCD Rule 4002 (National Emission Standards for Hazardous Air Pollutants)**—This rule incorporates by reference the National Emission Standards for Hazardous Air Pollutants from Part 61, Chapter I, Subchapter C, Title 40, Code of Federal Regulations (CFR) and the National Emission Standards for Hazardous Air Pollutants for Source Categories from Part 63, Chapter I, Subchapter C, Title 40, Code of Federal Regulations (CFR).
- **SJVAPCD Rule 4102 (Nuisance)**—This rule prohibits discharge from any source whatsoever such quantities of air contaminants or other materials which cause injury, detriment, nuisance or annoyance to any considerable number of persons or to the public or which endanger the comfort, repose, health or safety of any such person or the public or which cause or have a natural tendency to cause injury or damage to business or property.
- **SJVAPCD Rule 4201 and Rule 4202 (Particulate Matter Concentration and Emission Rates)**—These rules provide PM emission limits for sources operating within the district.
- **SJVAPCD Rule 4301 (Fuel-Burning Equipment)**—This rule limits the emissions from fuel-burning equipment whose primary purpose is to produce heat or power by indirect heat transfer.
- **SJVAPCD Rule 4601 (Architectural Coatings)**—This rule limits VOC emissions from architectural coatings.
- **SJVAPCD Rule 4641 (Cutback, Slow Cure, and Emulsified Asphalt, Paving, and Maintenance Operations)**—This rule limits VOC emissions by restricting the application and manufacturing of certain types of asphalt for paving and maintenance operations.
- **SJVAPCD Rule 8011 (General Requirements—Fugitive Dust Emission Sources)**—This rule outlines requirements for implementation of control measures for fugitive dust emission sources.
- **SJVAPCD Rule 9510 (Indirect Source Review)**—This rule outlines mitigation requirements for construction and operations emissions that exceed certain thresholds. The rule applies to any transportation project in which construction emissions equal or exceed 2 tons of NO_X or PM_{10} per year. Projects subject to Rule 9510 must submit an Air Impact Assessment application to the SJVAPCD prior to construction.
- **BAAQMD and SJVAPCD CEQA Guidelines—**The BAAQMD and SJVAPCD prepared their *Air Quality Guidelines* and *Guide for Assessing and Mitigating Air Quality Impacts* (GAMAQI), respectively, to assist lead agencies and project applicants in evaluating the potential air quality impacts of projects in the SFBAAB and SJVAB (BAAQMD 2017b; SJVAPCD 2015). The Air Quality Guidelines and GAMAQI provide BAAQMD- and SJVAPCD-recommended procedures for evaluating potential air quality impacts during the CEQA environmental review process. The documents provide guidance on evaluating short-term (construction) and long-term (operational) air emissions. The Air Quality Guidelines and GAMAQI used in this evaluation contain guidance on the following:
  - Criteria and thresholds for determining whether a project may have a significant adverse air quality impact
  - Specific procedures and modeling protocols for quantifying and analyzing air quality impacts

- Methods to mitigate air quality impacts
- Information for use in air quality assessments and environmental documents that will be updated more frequently, such as air quality data, regulatory setting, climate, and topography
- USEPA Rule 40 C.F.R. Part 89, Control of Emissions from New and In-Use Nonroad Compression-Ignition Engines: requires stringent emission standards for mobile nonroad diesel engines of almost all types using a tiered phase-in of standards
- CARB Rule 13 California Code of Regulations Section 1956.8, California Exhaust Emission Standards and Test Procedures for 1985 and Subsequent Model Heavy-Duty Diesel Engines and Vehicles: requires significant reductions in emissions of NO_X, PM, and nonmethane organic compounds using exhaust treatment on heavy-duty diesel engines manufactured in model year 2007 and later years.

12 ESTIMATED EMISSION RATES AND COMPARISON TO *DE MINIMIS* THRESHOLDS—CUMULATIVE ANALYSIS

The RSA for cumulative air quality impacts is the SFBAAB and SJVAB. While these are separate projects for purposes of planning the HSR system, construction of the Project would overlap with the construction period for the following other HSR sections[13]:

- San Francisco to San Jose, construction in the SFBAAB between 2022 and 2025
- Merced to Fresno, construction in the SJVAB in 2022
- Central Valley Wye, construction in the SJVAB in 2022 and material hauling in the SFBAAB in 2022
- Fresno to Bakersfield, construction in the SJVAB between 2022 and 2023
- Bakersfield to Palmdale, construction in the SJVAB between 2022 and 2025

Overlapping construction activities could add to cumulative air quality impacts within the SFBAAB and SJVAB. For purposes of full disclosure of the potential impacts, the cumulative emissions that could result from potential concurrent construction activities are presented in Tables 9 and 10. As the analysis demonstrates, concurrent construction could result in exceedances of the NO_X General Conformity *de minimis* threshold in the SFBAAB and VOC and NO_X General Conformity *de minimis* thresholds in the SJVAB. As previously discussed, the Authority has already entered into an MOU with the SJVAPCD that will offset all emissions of VOC, NO_x, and PM generated in the SJVAB by construction of the High Speed Rail Project to net zero. Pursuant to AQ-MM#-3, the Authority will enter into an agreement with BAAQMD to offset VOC and NOx emissions from construction of the Project in excess of the federal *de minimis* thresholds to net zero, if there will be exceedances of the VOC or NOx thresholds as determined by an analysis to be conducted prior to the issuance of construction contracts.

The Merced to Sacramento Project would also generate emissions in the SJVAB. However, this section would not be completed until Phase 2, which is after the mandated Los Angeles to San Francisco line. It is likely construction activities would therefore take place after this Project is completed (i.e., after 2028).

[13] The analysis assumed that Project construction would take place from 2022 to 2028, and that construction of other HSR project sections would occur according to the schedules presented in their respective environmental documents.

Table 9 Overlapping HSR System Construction Emissions in the SFBAAB (tons per year)

13 REPORTING AND PUBLIC COMMENTS

To support a decision concerning the Project, the FRA is issuing this draft General Conformity Determination for a 30-day public ad agency review. In developing the analysis underlying this general conformity determination, the Authority has consulted extensively with the BAAQMD and SJVAPCD on a variety of technical and modeling issues. The Authority has also consulted with the USEPA and CARB on the overall approach to demonstrating general conformity.

The FRA has provided copies of the draft General Conformity Determination to the appropriate regional offices of the USEPA, CARB, BAAQMD, and SJVAPCD for a 30-day review. The FRA will also issue a notice in the *Federal Register* announcing the availability of the draft general conformity determination and requesting written public comments during a 30-day period. This draft conformity determination will be made available on FRA's docket at https://www.regulations.gov/, Docket FRA-2021-X.

Any comments on the draft General Conformity Determination will be included in the Final EIR/EIS for the Project and will be addressed in the Final General Conformity Determination.

This Page Intentionally Left Blank

14 FINDINGS AND CONCLUSIONS

FRA conducted a General Conformity evaluation consistent with 40 C.F.R. Part 93 Subpart B. The General Conformity regulations apply at this time to this Project because the Project is in an area that is designated as either nonattainment or maintenance for the 8-hour O_3, 24-hour $PM_{2.5}$, and 24-hour PM_{10} standards. The FRA conducted the General Conformity evaluation consistent with all regulatory criteria and procedures and following the Authority's coordination with the USEPA, BAAQMD, SJVAPCD, and CARB. As a result of this review, the FRA concluded, because Project-generated emissions would either be fully offset (for construction phase) or less than zero (for operational phase), that the Project's emissions can be accommodated in the SIP for the SFBAAB and SJVAB. The FRA has determined that the Project as designed would conform to the approved SIP based on the following:

- The Authority would commit that construction-phase NO_X emissions would be offset consistent with the applicable federal regulations by entering into an agreement with BAAQMD and through the Authority's existing commitments in its June 2014 MOU and VERA with the SJVAPCD, respectively.
- The Authority, BAAQMD, and SJVAPCD would enter into a contractual agreement to mitigate the Project's NO_X emissions by providing funds to BAAQMD's and SJVAPCD's to fund grants for projects that achieve the necessary emission reductions.
- BAAQMD and SJVAPCD would seek and implement the necessary emission reduction measures, using Authority funds.
- BAAQMD and SJVAPCD would serve as administrators of the emissions reduction projects and verifiers of the successful mitigation effort.

Therefore, the FRA intends to issue a final determination that concludes that the Project, as designed, conforms to the purpose of the approved SIP and is consistent with all applicable requirements.

1 INTRODUCTION

This document provides additional information regarding the benefits associated with the long-term operation of the high-speed rail (HSR) project. The document briefly summarizes assumptions about the HSR system and the corresponding key project benefit information that was presented in the San Jose to Merced Section Project Environmental Impact Report (EIR)/Environmental Impact Statement (EIS). The benefits described in the EIR/EIS are based on the scenarios and assumptions contained in the 2016 Business Plan, which was adopted by the California High-Speed Rail Authority (Authority) Board on May 1, 2016. This document provides information on how those benefits may change based on updated scenarios and assumptions contained in the 2018 Business Plan, which was adopted by the Authority Board on May 15, 2018. This information is intended to reflect the potential range of outcomes for HSR project benefits in the future and to inform the decision-making process.

The information contained in this appendix is part of the EIR/EIS. However, it does not constitute a change in the proposed HSR system and does not identify new or more severe adverse environmental impacts or changes to the discussion of adverse environmental impacts from the HSR system. The additional information does not change the feasibility of any alternatives or mitigation strategies that were considered infeasible or not reasonable for purposes of project-level analysis. This additional information is solely for the purpose of providing a comparison of the analysis provided in the EIR/EIS to the 2018 Business Plan.

2 OVERVIEW OF KEY ASSUMPTIONS IN THE 2016 AND 2018 BUSINESS PLANS

2.1.1 2016 Business Plan

The EIR/EIS includes information on project benefits, including reduced vehicles miles traveled (VMT), energy use, and air pollution. These benefits were derived based on the assumptions in the 2016 Business Plan for the opening year for passenger service of the Silicon Valley to Central Valley Line (Valley-to-Valley Line) and Phase 1 of the HSR System (Phase 1). The Valley to Valley Line would connect San Jose to north of Bakersfield. Phase 1 would connect San Francisco and the Bay Area to Los Angeles and Anaheim.

Two primary forecasting scenarios were created: one assumes that the Valley-to-Valley line would open in 2025 and the other assumes that Phase 1 would begin in 2029. Forecasts were also made for 2040, the planning horizon for the environmental analysis. A 5-year ramp-up assumption was made for growth in ridership after the opening of each section for revenue service. It was assumed that only 40 percent of the forecast ridership would materialize in the first year, 55 percent in the second, 70 percent in the third, 85 percent in the fourth, and 100 percent in the fifth.

Because the ultimate ridership of the HSR system would depend on many uncertain factors, such as the price of gasoline and population growth, the forecasts in the 2016 Business Plan and EIR/EIS consider medium and high ridership scenarios for each analysis year.

2.1.2 2018 Business Plan

The 2018 Business Plan builds on and updates the 2016 Business Plan. It summarizes the progress made since 2016, updates information and forecasts, and outlines a path for advancing the HSR project. The revised cost estimates and forecasts have been informed by and improved through rigorous scrutiny and review by a range of external experts and academics. The 2018 Business Plan also includes an updated analysis of the economic impacts of the system, which shows that the program is financially viable and a sound investment opportunity.

One of the key revisions to the 2018 Business Plan that could affect the benefits analysis presented in the EIR/EIS is opening year assumption for the Valley-to-Valley Line and Phase 1. In its 2016 Business Plan, the Authority adopted the goal of completing a connection between San Jose to north of Bakersfield as part of the initial Valley-to-Valley Line. The 2018 Business Plan extends the Valley-to-Valley Line with service between San Francisco and Bakersfield.

Extending the Silicon Valley to Central Valley Line to San Francisco and Bakersfield expands high-speed rail to major urban centers at both ends of the line, which results in different ridership forecasts than the Valley-to-Valley Line as defined in the 2016 Business Plan. The extended Valley-to-Valley Line would not be complete until 2029. Accordingly, the opening year for Phase 1, which includes the sections from Bakersfield to Anaheim, from Madera to Merced, and final improvements between San José to San Francisco (Salesforce Transit Center), was updated in the 2018 Business Plan to 2033. As discussed above, the EIR/EIS assumed that the Valley-to-Valley line would begin operating and generating benefits in 2025 and Phase 1 would begin in 2029.

In addition to different opening years, the 2018 Business Plan presents different ridership forecasts for 2029 and 2040 than were assumed in the EIR/EIS. All forecasts presented in the 2018 Business Plan used the same models as the 2016 Business Plan. However, since the 2016 Business Plan, the ridership model has gone through additional internal and external reviews. In addition, key model inputs for all forecasting have been updated to reflect the latest available data, such as population forecasts and auto operating costs. Specifically, input data were updated for the following:

- Socioeconomic forecasts
- Transit network plans
- Auto travel time
- Auto operating cost
- Parking costs
- Operations planning

Finally, the ridership forecast includes an enhanced risk analysis that considers new and additional risk variables. This enhanced risk analysis builds upon the risk analysis conducted in 2016 by including the following risk variables:

- **Reliability of high-speed rail**—Capturing uncertainty around on-time reliability
- **Travel time in autonomous vehicles**—Measuring the disutility of time spent in an automobile and considers how travel choices might change with autonomous vehicles
- **Visitor travel**—Including out-of-state trips from tourism, business, and other travel
- **Induced travel**—Including trips that would not have otherwise been made without the increased connections created by the HSR system
- An enhanced penalty applied to long-distance HSR trips that require long access/egress travel time

2.1.3 Ridership Comparison

Based on the assumptions of the 2016 Business Plan, the EIR/EIS presents ridership forecasts for the initial segment of the Valley-to-Valley line in 2025 under the medium and high ridership forecasts. The EIR/EIS also presents ridership forecasts for Phase 1 in 2029 and the 2040 planning horizon. Table 1 presents a comparison of the ridership forecasts from the 2016 and 2018 Business Plans.

Based on the assumptions of the 2018 Business Plan, the extended Valley-to-Valley line would open in 2029 and carry 71 percent fewer annual riders compared to the HSR system described in the 2016 Business Plan. The ridership comparison for 2029 is not exact given that the 2016 Business Plan assumes Phase 1 would be open by 2029 and the 2018 Business Plan assumes that only the extended Valley-to-Valley line would be open by 2029. The most direct and applicable comparison is under 2040 conditions where both the 2016 and 2018 Business Plans assumed full build of the HSR system. As shown in Table 1, the 2018 Business Plan forecasts 9 to 18 percent fewer annual riders in 2040 than the 2016 Business Plan.

Table 2 Comparison of High-Speed Rail System Ridership Forecasts Under the 2016 and 2018 Business Plans (millions of riders per year)

Forecasts	2025[1]	2029[2,3]	2033[4]	2040[5]
Medium Ridership				
2016 Business Plan	3.0	19.3	-	42.8
2018 Business Plan	-	5.7	23.6	40.1
Change	*N/A*	*-71%*	*N/A*	*-18%*
High Ridership				
2016 Business Plan	4.2	26.0	-	56.8
2018 Business Plan	-	7.6	30.8	51.6
Percent Change (%)	*N/A*	*-71%*	*N/A*	*-9%*

Sources: Authority 2016, 2018a
- = data not available
N/A = comparison not available
[1] 2016 Business Plan assumes Valley-to-Valley line will be open by 2025.
[2] 2016 Business Plan assumes Phase 1 will be open by 2029.
[3] 2018 Business Plan assumes extended Valley-to-Valley line will be open by 2029.
[4] 2018 Business Plan assumes Phase 1 will be open by 2033.
[5] Both the 2016 and 2018 Business Plans use 2040 as the environmental analysis planning horizon.

3 COMPARSION OF KEY PROJECT BENEFITS UNDER THE 2016 AND 2018 BUSINESS PLANS

Ridership estimates from the 2016 Business Plan (see Table 1) were used in the EIR/EIS to assess project benefits under the medium and high rider forecasts for 2029 and 2040 in terms of reduced VMT, air quality emissions, and energy consumption, as compared to the No Project Alternative (Authority 2018). Table 2 presents a summary of these key benefits. Note that criteria pollutant reductions are not shown as all pollutants would be reduced for all years and under all ridership forecasts. Refer to Table 3.3-22 and Table 3.3-23 in Section 3.3, Air Quality and Greenhouse Gases, for estimated criteria pollutant reductions.

Table 1 Summary of Key EIR/EIS Annual Statewide Benefits Compared to the No Project Alternative

Forecast	VMT (million miles)	Diverted Aircraft Flights	GHG Emissions (million metric tons CO_2e)	Energy Use (million BTUs)
2029				
Medium Ridership	2,300	52,000	0.5	11.7
High Ridership	3,100	58,000	0.3	9.5
2040				
Medium Ridership	4,800	111,000	1.0	19.3
High Ridership	6,600	107,000	1.5	28.1

VMT = vehicle miles traveled
CO_2e = carbon dioxide equivalent
BTU = British thermal unit

The HSR project would provide a new travel mode and divert automobile trips and aircraft flights to the HSR. The reduction in both automobile and air travel VMT would provide benefits in the form of reduced congestion on both the state's highway system as well as at airports. Shifting

passenger trips to HSR would also achieve substantial criteria pollutant and GHG emissions reductions, as well as energy savings. Under the 2018 Business Plan ridership forecasts, the HSR project would achieve these benefits, but they would occur at different times and may be less than described in the EIR/EIS under Phase 1 in 2040.

The EIR/EIS assumes that Phase 1 would open in 2029, whereas the 2018 Business Plan assumes that in 2029, only the Valley-to-Valley line would be open. This results in about 70 percent fewer riders in 2029 as compared to the EIR/EIS, which would likely lower estimated VMT and aircraft reductions in this year by a similar percentage. However, once Phase 1 is completed in 2033, the project would yield the same types of Phase 1 ridership benefits as presented in the EIR/EIS.

Under Phase 1 in 2040, the 2018 Business Plan estimates that the HSR project would achieve 9 to 18 percent fewer annual riders than expected under the 2016 Business Plan. Because project benefits in the form of reduced VMT, air pollution, GHG emissions, and energy use are based on the public's use of the HSR system, it is reasonable to expect that the lower ridership forecasts of the 2018 Business Plan scenarios (see Table 1) would lead to benefits in these areas accruing more slowly than anticipated in the EIR/EIS (see Table 2). Accordingly, benefits achieved under the 2018 Business Plan may be 9 to 18 percent less than those presented in the EIR/EIS, depending on the ridership scenario.

4 OTHER POTENTIAL BENEFITS

Additional benefits of the HSR project described in the EIR/EIS and 2018 Business Plan include:

- Travel time savings for HSR riders
- Travel time savings for highway users
- Travel time savings for airline passengers
- Reliability in travel times
- Reductions in vehicle operating costs
- Increased productivity for HSR riders
- Reduction in parking infrastructure needs
- Airline operator savings
- Improved transportation safety and reduced costs from accidents
- Jobs to operate and maintain the HSR system

In the 2014 Business Plan, a benefit-cost analysis concluded that the anticipated quantifiable benefits from the HSR system exceed anticipated costs, regardless of buildout phasing or scenarios (Authority 2014). This is true for assumptions in both the 2016 and 2018 Business Plans. However, the quantifiable benefits achieved under the 2018 Business Plan may follow the same trend of ridership and be 71 percent less in 2029 and 9 to 18 percent less in 2040 than the quantifiable benefits presented in the 2016 Business Plan.

5 CONCLUSION

Although the 2018 Business Plan assumes fewer annual riders in 2029 and 2040 and therefore reduced benefits when compared to the 2016 Business Plan, in both business plans the HSR ultimately affords a more energy-efficient choice for personal travel that will help alleviate highway congestion and provide greater capacity for goods movement. Benefits would be achieved in terms of reduced VMT, air quality emissions, and energy consumption. With the HSR as a backbone for the state's transportation infrastructure, there are also new opportunities for transit connectivity and refocusing land use patterns that can take advantage of mass transit investment and other alternatives to automobile travel, reducing GHG emissions and moving the state closer to the "sustainable community" goals laid out in Senate Bill 375 (see Chapter 1 of the EIR/EIS).

EXECUTIVE SUMMARY

The California High-Speed Rail Authority (Authority) has prepared this *San Jose to Merced Project Section Noise and Vibration Technical Report* to support the *San Jose to Merced Project Section Final Environmental Impact Report (EIR)/Environmental Impact Statement (EIS).* This technical report characterizes existing conditions and analyzes noise and vibration effects of four alternatives.

This technical report addresses effects resulting from construction and operations of the San Jose to Merced Project Section (Project Section or project), focusing on the portion of the Project Section between San Jose and Carlucci Road (San Jose to Central Valley Wye Project Extent, or simply the project). It describes relevant federal, state, regional, and local regulations and requirements; methods used for the analysis of effects; the affected environment; impact avoidance and minimization features (IAMF) incorporated into the project design that would avoid, minimize, or reduce specific environmental effects; and the potential effects of noise and vibration in the resource study area (RSA) that would result from construction and operations of the project alternatives. Project noise and vibration effects consist of construction-related noise and vibration effects, high-speed rail (HSR) operations noise and vibration effects, including noise from stations and maintenance facilities, and operations traffic noise effects.

Summary of Effects

This analysis evaluates noise and vibration impacts[1] associated with the four project alternatives for both the construction and operations phases. Construction of the project, including Pacific Gas and Electric (PG&E) network upgrades, would require the use of mechanical equipment that would generate temporary increases in noise and ground-borne vibration and result in temporary construction impacts at noise-sensitive locations. The Authority and its contractors would comply with Federal Transit Administration (FTA) and Federal Railroad Administration (FRA) guidelines for minimizing noise and vibration impacts at sensitive receptors during project construction (NV-IAMF#1: Noise and Vibration), but construction noise and vibration effects would remain.

Project operations would permanently increase noise levels above existing ambient noise levels, potentially resulting in environment noise impacts at sensitive receptors. Alternative 4 would have the most severe and moderate operations noise impacts, followed by Alternative 2, Alternative 1, and Alternative 3 under the 2040 Plus Project conditions. Under the 2040 Plus Project condition, there would be 337 severe noise impacts and 1,200 moderate impacts under Alternative 1; there would be 755 severe impacts and 1,844 moderate impacts under Alternative 2; there would be 222 severe impacts and 834 moderate impacts under Alternative 3; and there would be 1,212 severe impacts and 1,666 moderate impacts under Alternative 4.

With the Diridon design variant (DDV) and tunnel design variant (TDV) under the 2040 Plus Project condition, there would be 347 severe noise impacts and 1,195 moderate impacts under Alternative 1; there would be 766 severe impacts and 1,838 moderate impacts under Alternative 2; there would be 233 severe impacts and 845 moderate impacts under Alternative 3; and there would be 1,224 severe impacts and 1,658 moderate impacts under Alternative 4.

Project operations would generate traffic and associated noise at HSR stations. Near the San Jose Diridon Station, the largest day-night sound level (L_{dn}) contribution from the parking facilities at nearby noise receptors would be 29 A-weighted decibels (dBA). Near the Downtown Gilroy Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 40 dBA. Near the East Gilroy Station, the largest L_{dn} contribution from the parking facilities at nearby noise receptors would be 28 dBA. The additional noise from parking facilities would be substantially lower (at least 18 dBA lower) than the projected L_{dn} from project operations.

[1] The terms *impact* and *effect* have the same meaning in this document. The use of the term “impact” in this document does not imply that the impact is necessarily significant as defined in NEPA or CEQA. Instead, the term refers to an effect that may exceed a relevant FRA or FTA impact criteria level. The significance impact determinations are made in the EIR/EIS section and not in this document.

Project operations would also generate additional noise associated with train movements in and out of the maintenance of way facility (MOWF) near Gilroy. Under Alternatives 1 and 2, the L_{dn} contribution from the South Gilroy MOWF at the nearest receptor would be 40 dBA (more than 20 dBA below HSR operations). Under Alternative 3, the L_{dn} contribution from the East Gilroy MOWF at the nearest receptor would be 47 dBA (more than 20 dBA below HSR operations). Under Alternative 4, the L_{dn} contribution from the MOWF at that nearest receptor would be 45 dBA (i.e., more than 18 dBA below HSR operations). The MOWFs would not contribute to noise impacts of nearby sensitive receptors under any of the alternatives.

The potential for passing HSR train noise to startle or surprise humans near the HSR track and result in human annoyance is included in this analysis as "additional information" per FRA guidance (FRA 2012). Annoyance and startle effects for humans would be primarily limited to areas within the project's proposed right-of-way and limited areas adjacent to the right-of-way. Analysts also evaluated the potential for livestock to experience stress associated with the noise of passing trains in exceedance of the FRA's recommended threshold. Livestock within approximately 30 feet of the edge of the HSR right-of-way would experience startle effects and stress from train passbys, and livestock within 65 feet of horn-sounding locations would experience startle effects and stress from horn sounding. Noise effects on wildlife are evaluated separately in the *San Jose to Merced Project Section Biological and Aquatic Resources Technical Report* (Authority 2019a).

Construction of the project would result in temporary and permanent changes in the local roadway network that would require some diversion and rerouting of traffic. The diversion of traffic would not be expected to affect noise levels because traffic on local roadways provides only a minor contribution to overall noise levels.

Project operations would generate additional traffic and traffic-related noise under the 2029 Plus Project and 2040 Plus Project conditions. Permanent increases in traffic-related noise would be similar for all four alternatives and would occur at roadway segments near San Jose Diridon Station, along Monterey Corridor, and near Gilroy. In 2029, seven roadway segments under Alternatives 1 and 2 and six roadway segments under Alternatives 3 and 4 would have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. In 2040, operations of each project alternative would result in 12 roadway segments with the potential for noise level increases greater than or equal to 3 dB. The majority of these traffic noise impacts would occur near the San Jose Diridon Station and along Monterey Road.

Traction power facilities would generate noise, potentially affecting receptors within 110 feet of TPF serving the Project (2029 and 2040). In all cases, receptors would also be affected by HSR train operations TPF operations would not result in moderate or severe noise impacts on their own (absent train operations) for any alternative.

Construction of the project would require the use of mechanical equipment that would generate temporary increases in ground-borne vibration which could result in human annoyance and building damage. Construction activities, such as pile driving, would have the potential to cause structural damage to buildings close to these activities (within 50 feet). Most construction activities would only have the potential to cause annoyance from vibration within 160 feet of the mechanical equipment. Some equipment, such as pile driving or ongoing demolition work would have the potential to cause annoyance from vibration within 300 feet. Construction of tunnels in the Pacheco Pass Subsection would have the potential to generate temporary increases in ground-borne vibration that would reach 64 VdB at the closest receptor at 200 feet slant distance and would not be perceptible in buildings proximate to the tunnel boring machine (TBM) operations.

Project operations would have the potential to result in permanent increases in vibration levels at sensitive receptors. The evaluation of potential vibration impacts for the project alternatives indicates that there is a greater potential for vibration impacts associated with Alternative 4, followed by Alternative 2, Alternative 3, and Alternative 1.

1 INTRODUCTION

Since publication of the Draft Environmental Impact Report (EIR)/Environmental Impact Statement (EIS), the following substantive changes have been made to this appendix:

- Where appropriate, the verb "would," when used specifically to describe impact avoidance and minimization features (IAMF) or mitigation measures, as well as their directly related activities, was changed to "will," indicating their integration into project design.
- A typographic error in the noise measurement data for noise measurement location N128 was corrected in Table 5-1. Corrections to Figures B-168, B-169, and B-170 for this measurement site were made in Appendix B, Noise Measurement Data, and Draft EIR/EIS Figure B-171 for this measurement site was deleted.
- Analysis about the DDV and TDV was included in this appendix. Figures 5-9, 5-11, 5-13, 5-17, 5-21, and 5-25 were added to illustrate these effects, and Tables 5-6, 5-7, 5-8, 5-9, 5-10, 5-11, 5-12, and 5-13 were updated to include effects of the DDV and TDV.
- As a result of public comments, revisions were made to the Alternative 4 noise impact assessment to correct errors in the analysis. This changed the number of noise impacts in the San Jose Diridon Station Approach, Monterey Corridor, and the Morgan Hill and Gilroy Subsections. Changes were made to Figures 5-22, 5-23, and 5-24 and Tables 5-6, 5-7, and 5-8.
- Changes were made to Figures 5-6, 5-7, 5-8, 5-14, 5-15, 5-16, 5-18, 5-19, and 5-20.
- Additional noise-sensitive receptors were identified and determined to have noise impacts under all alternatives in the Pacheco Pass and San Joaquin Valley Subsections. Changes were made to Figures 5-10, 5-11, 5-12, and 5-13 and Tables 5-6, 5-7, and 5-8.

This report presents a noise and vibration technical evaluation for the California High-Speed Rail San Jose to Merced Project Section (Project Section or project), focusing on the portion of the Project Section between San Jose and Carlucci Road (San Jose to Central Valley Wye Project Extent, or simply the project), prepared in support of environmental reviews required under the National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA).

1.1 Background of the HSR Program

The California High-Speed Rail Authority (Authority) proposes to build, operate, and maintain an electric-powered high-speed rail (HSR) system in California, connecting the San Francisco Bay Area and Central Valley to Southern California. When completed, the nearly 800-mile train system would provide new passenger rail service to more than 90 percent of the state's population. More than 200 weekday trains would serve the statewide intercity travel market. The system would be capable of operating speeds up to 220 miles per hour (mph) in certain HSR sections, with state-of-the art safety, signaling, and automatic train control systems. The California HSR System would connect and serve the state's major metropolitan areas, extending from San Francisco to Los Angeles and Anaheim in Phase 1, with extensions to Sacramento and San Diego in Phase 2.

The Authority and Federal Railroad Administration (FRA) commenced their tiered environmental planning process with the *2005 Final Program Environmental Impact Report (EIR)/Environmental Impact Statement (EIS) for the Proposed California High-Speed Train System* (Statewide Program EIR/EIS) (Authority and FRA 2005), followed by the *Bay Area to Central Valley High-Speed Train Final Program EIR/EIS* (Authority and FRA 2008). These documents established the HSR sections constituting the California HSR System and evaluated the impacts of proposed HSR corridors. After completion of the first-tier programmatic environmental documents, the Authority and FRA approved the HSR system, selected corridors and stations for further study, and began preparing second-tier project environmental evaluations for sections of the statewide HSR system. Chapter 2, Description of the San Jose to Central Valley Wye Project Extent, provides details of the project and the four alternatives under consideration.

1.2 Purpose of this Technical Report

This report supports the San Jose to Merced Project Section Final EIR/EIS. The resource assessment presented in this report is consistent with the Authority and FRA's *California High Speed Rail Project EIR/EIS Environmental Methodology Guidelines Version 5.09* (Version 5 Environmental Methods), adopted in April 2017 (Authority and FRA 2017) and the following federal guidelines established by the FRA, Federal Transit Administration (FTA), and Federal Highway Administration (FHWA):

- ***High-Speed Ground Transportation Noise and Vibration Impact Assessment* (FRA guidance manual) (FRA 2012)—** Establishes guidelines for the evaluation of noise and vibration impacts associated with HSR trains;
- ***Transit Noise and Vibration Impact Assessment* (FTA guidance manual) (FTA 2018)—** Establishes methodology applicable to HSR station activities, yard and maintenance facility activities, and conventional-speed rail operations;
- ***Roadway Construction Noise Model* (FHWA 2006)—**Guidance used in conjunction with the FRA guidance manual to assess construction noise.

1.3 Organization of this Technical Report

This technical report comprises the following chapters in addition to this introductory chapter:

- Chapter 2 describes the project alternatives as currently proposed.
- Chapter 3, Laws, Regulations, and Orders, describes federal, state, regional and local laws, regulations, and policies relevant to noise and vibration.
- Chapter 4, Methods for Evaluating Effects, provides an overview of noise and vibration descriptors, describes the noise and vibration resource study area (RSA), the impact assessment criteria, and the noise and vibration prediction methodology used in the assessment.
- Chapter 5, Existing Conditions and Effects Analysis, describes the environmental setting and assesses the construction and operations effects related to noise and vibration.
- Chapter 6, References, provides complete reference information for the published, online, agency, institutional, and individual sources consulted in preparation of this report.
- Chapter 7, Preparer Qualifications, presents the credentials of the staff who oversaw the preparation of this report.
- Supporting information is provided in the following appendices:
  - Appendix A, Measurement Site Photographs
  - Appendix B, Noise Measurement Data
  - Appendix C, Vibration Propagation Measurement Data

2 DESCRIPTION OF THE SAN JOSE TO CENTRAL VALLEY WYE PROJECT

The Project Section would provide HSR service between Diridon Station in downtown San Jose and a station in downtown Merced, with a Gilroy station either in downtown Gilroy or east of Gilroy. The Project Section is designed to allow trains to and from the Bay Area to transition smoothly from north-south to east-west travel with a minimum reduction in speed to achieve the Proposition 1A operational service time requirement. Proposition 1A requires that the system be designed to be capable of a nonstop operational service time of 2 hours and 10 minutes between San Jose and Los Angeles Union Station.[2] The Project Section follows existing transportation corridors to the extent feasible, as directed by Proposition 1A.[3]

The Project Section is comprised of three project extents (Figure 2-1):

- From Scott Boulevard in Santa Clara to Carlucci Road in Merced County, at the western terminus of the Central Valley Wye (the project)
- The Central Valley Wye, which connects the east-west portion of HSR from the Bay Area to the Central Valley with the north-south portion from Merced to Fresno
- The northernmost portion of the Merced to Fresno Project Section, from the northern limit of the Central Valley Wye (Ranch Road) to the Merced Station

The project would connect San Jose to the Central Valley portion of the HSR system at the Central Valley Wye in Merced County, which in turn connects to the portion of the system running north to Merced and south to Fresno and Southern California. Because the portion of the Project Section between Carlucci Road and Merced has been analyzed in the *Merced to Fresno Section Final EIR/EIS* (Authority and FRA 2012) and the *Merced to Fresno Section: Central Valley Wye Supplemental EIR/EIS* (Authority 2019b), the analysis in this document focuses on the project extent between Scott Boulevard and Carlucci Road (the project).

[2] Proposition 1A requires that the HSR system be designed to achieve a nonstop operational service time of 2 hours and 40 minutes between San Francisco and Los Angeles Union Station, including a 30-minute ride between San Francisco and San Jose (Streets & Highways Code § 2704.09(b)(4)).

[3] Proposition 1A directs that the HSR system maximize use of existing transportation and utility corridors to the extent feasible (Streets & Highways Code § 2704.09(g)).

Figure 2-1 Proposed San Jose to Merced Project Section

2.1 Summary of Design Features

While the northern service limit of the project would be the San Jose Diridon Station, the engineering design and evaluation includes infrastructure and train operations north to Scott Boulevard to serve the San Jose Diridon Station; this additional analysis overlaps with the analysis of the San Francisco to San Jose Project Section to the north. The project is an approximately 90-mile portion of the 145-mile-long Project Section, which includes dedicated or blended[4] HSR track and systems; HSR stations located at San Jose Diridon and Gilroy; a maintenance of way facility (MOWF) in the Gilroy area; and a maintenance of way siding (MOWS) near Turner Island Road in the Central Valley (Figure 2-2). HSR stations at San Jose Diridon and Gilroy would support transit-oriented development, provide an interface with regional and local mass transit services, and provide connectivity to the South Bay and Central Valley highway network.[5] While the northern service limit of the project would be the San Jose Diridon Station, the engineering design and evaluation includes train operations north to Scott Boulevard in Santa Clara to support the independent utility of an HSR station at Diridon Station and to describe the proposed interface of HSR alternatives with blended Caltrain railroad infrastructure. This additional analysis between San Jose Diridon Station and Scott Boulevard overlaps with the analysis of the San Francisco to San Jose Project Section to the north. Under three alternatives, the transition of HSR infrastructure and operations from the blended system between San Francisco and Santa Clara to a fully dedicated system south of the San Jose Diridon Station would occur at either Scott Boulevard or near Interstate (I-) 880. A fourth alternative would extend the blended system through San Jose to Gilroy. The project would extend south from San Jose to Gilroy, then east through the Pacheco Pass to the Central Valley to end at Carlucci Road, the western boundary of the Central Valley Wye.

4 *Blended* refers to operating HSR trains with existing intercity, commuter, and regional trains on shared infrastructure.

5 *South Bay* refers to Santa Clara County.

JUNE 2019

Figure 2-2 Overview of Subsection Design Options

The project comprises the following five subsections:

- **San Jose Diridon Station Approach**—Extends approximately 6 miles from north of San Jose Diridon Station at Scott Boulevard in Santa Clara to West Alma Avenue in San Jose. This subsection includes San Jose Diridon Station and overlaps the southern portion of the San Francisco to San Jose Project Section.
- **Monterey Corridor**—Extends approximately 9 miles from West Alma Avenue to Bernal Way in the community of South San Jose. This subsection is entirely within the city of San Jose.
- **Morgan Hill and Gilroy**—Extends approximately 30–32 miles from Bernal Way in the community of South San Jose to Casa de Fruta Parkway/State Route (SR) 152 in the community of Casa de Fruta in Santa Clara County.
- **Pacheco Pass**—Extends approximately 25 miles from Casa de Fruta Parkway/SR 152 to I-5 in Merced County.
- **San Joaquin Valley**—Extends approximately 18 miles from I-5 to Carlucci Road in unincorporated Merced County.

The Authority and FRA have developed four end-to-end alternatives for the project (Figure 2-2). Table 2-1 shows the design options that distinguish the alternatives by subsection; Figures 2-3 through 2-7 illustrate the features of the four alternatives by subsection.

2.2 Description of Alternatives

This section describes the proposed design options of the project alternatives in each subsection. The alternatives are similar in length, differing only in the Morgan Hill and Gilroy Subsection, where divergent alignments in Morgan Hill and the alternative alignments through the Downtown Gilroy Station and the East Gilroy Station result in linear variations.

2.2.1 Alternative 1

Development of Alternative 1 was intended to minimize the project footprint, minimize ground disturbance, minimize continuous surface features, and decrease necessary right-of-way acquisition through extensive use of viaduct structures and bypassing downtown Morgan Hill. The HSR alignment for this alternative would consist of 45.4 miles of viaduct, 4.3 miles at grade, 21.9 miles of embankment, two tunnels totaling 15.0 miles, and 2.3 miles in trench.

2.2.1.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

The San Jose Diridon Station Approach Subsection, from Scott Boulevard in Santa Clara to West Alma Avenue in San Jose, would be approximately 6 miles through the cities of Santa Clara and San Jose (Figure 2-3). The existing Caltrain track in this subsection consists of a predominantly two-track and three-track at-grade alignment. South of De La Cruz Boulevard, the Union Pacific Railroad (UPRR) tracks of the Coast Line from the northeast converge with the Caltrain corridor tracks and continue south adjacent to the east side of the railroad corridor to the Santa Clara Caltrain Station. Between the Caltrain College Park Station and San Jose Diridon Station, Caltrain's Central Equipment Maintenance and Operations Facility comprises three mainline tracks, a maintenance building, and nine yard tracks. San Jose Diridon Station includes five passenger platforms served by nine yard tracks along the west side of the station house. HSR diverges from the Caltrain corridor at Park Avenue, just south of San Jose Diridon Station, and returns to the Caltrain corridor at the north end of the Caltrain Tamien Station, which includes a passenger platform served by two tracks and a single through-track.

Alternative 1 would begin at Scott Boulevard in blended service with Caltrain at grade. The blended service would entail several minor realignments of existing Caltrain track between Scott Boulevard and I-880. New UPRR and Caltrain track would be constructed just north of the HSR guideway beginning north of I-880 to just past the Santa Clara Station.

Beginning at I-880 on the southbound approach to West Hedding Street, Caltrain tracks would be realigned to accommodate the HSR tracks. Dedicated HSR tracks would diverge from the Caltrain Mainline Track (MT) 2 and MT3 tracks and continue southeast along the north side of the existing Caltrain corridor, crossing under West Hedding Street. To accommodate the new track configuration, the West Hedding Street roadway overpass would be replaced with a new overpass bridge that would also pass over Stockton Avenue.

Southeast of West Hedding Street, the dedicated HSR tracks would transition from a two-track at-grade configuration to retained fill and finally to a two-track aerial profile. The HSR alignment would begin the short viaduct option by rising on embankment to an approximately 70-foot-high aerial structure. A new bridge structure would be built to carry the realigned UPRR/Caltrain MT2 tracks over the West Taylor Street underpass. University Avenue would become a cul-de-sac. A new pedestrian underpass would be constructed near the alignment of Emory Street to allow Caltrain riders to reach both platforms of the Caltrain College Park Station. The HSR viaduct would also cross over West Taylor Street, then shift horizontally a maximum of 500 feet east of the existing UPRR/Caltrain mainline tracks to maintain high-speed track curvature.

Both legs of the UPRR Warm Springs Subdivision Lenzen Wye would be relocated, and North Montgomery Street would be extended north of the alignment of Lenzen Avenue almost to the former Lenzen Wye to maintain property access beneath the 60-foot-high HSR viaduct. The HSR viaduct would cross over Cinnabar Street, both legs of the relocated Lenzen Wye and North Montgomery Street, West Julian Street, and West Santa Clara Street while curving west toward

the UPRR/Caltrain mainline tracks to enter a new aerial dedicated HSR station at San Jose Diridon Station.

Continuing on an aerial structure, the alignment would diverge from the Caltrain right-of-way south of the San Jose Diridon Station HSR platforms by turning sharply east at the Park Avenue undercrossing of UPRR/Caltrain tracks. The HSR aerial structure would cross over Los Gatos Creek and San Carlos Street, then over Royal Avenue and the intersection of Bird Avenue and Auzerais Avenue, then over the I-280/SR 87 interchange. Continuing south along the east side of SR 87, the HSR aerial structure would cross over West Virginia Street and the Guadalupe River Trail, then over the Caltrain rail bridge, the Guadalupe River, and Willow Street. The HSR aerial structure would continue south over the Caltrain Tamien Station on an alignment between Tamien Station and the SR 87 freeway, transitioning to the Monterey Corridor Subsection at West Alma Avenue.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

The HSR San Jose Diridon Station would entail a four-track aerial alignment over the existing Diridon Station at approximately 62 feet to top of rail with 1,410-foot-long platforms above the existing Caltrain rail yard centered between Santa Clara Street and Park Avenue. The existing historic train station would remain in place. As illustrated on Figures 2-8 and 2-9, the primary HSR station building would be constructed north of the existing station building but would continue to the south, wrapping around the existing Caltrain station building. The HSR station building would be accessed from the east at three entrances—the main entrance on the east side of the tracks north of the existing Historic Depot next to the future Bay Area Rapid Transit (BART) alignment; an entrance south of the existing historic Diridon Station building; and an entrance on the east side south of the Pacific Gas and Electric Company (PG&E) power station. There would also be three entrances to the HSR station on the west side of the tracks—a north entrance at the end of White Street and two entrances on Laurel Grove Lane, one north and one south. The aerial station would require viaduct columns within the PG&E substation. The HSR station building would encompass 99,289 square feet with a 4,400-square-foot substation and systems building. The concourse would consist of a mezzanine level above the existing Caltrain tracks and below the HSR platforms, with three east-west connections across the tracks at the north, south, and middle.

Existing parking spaces (226) at Cahill Street would be displaced and replaced 1:1 with new parking areas at Cahill and Park Streets and at Stockton and Alameda Streets. HSR parking demand of 1,050 spaces in 2040 would be met by commercially available parking downtown or at the airport. The Authority has provided a Station Area Planning grant to the City of San Jose to advance the implementation of the Diridon Station Area Plan adopted by the San Jose City Council. Through this effort, the City would address short-term parking needs during HSR and BART Phase II construction and would also address plans for transitioning the parking needed during construction to the highest and best use after construction. Another Station Area Planning grant to the (Santa Clara) Valley Transportation Authority (VTA) would fund a San Jose Diridon Station Facilities Master Plan. This grant would develop a parking program to manage parking demand and supply over time to reflect changes in ridership and park-and-ride mode share. These two studies would provide input into a multimodal access plan for the station that would be developed prior to final station design and construction.

Existing underutilized parking capacity at and around the station would be used to meet the estimated HSR parking demand until a station area parking policy and program are implemented. The Authority would rely on commercially available parking to meet HSR parking demand, provided and priced in accordance with local conditions. HSR riders would be able to walk or take a shuttle, such as the City of San Jose's DASH, from parking located downtown or adjacent to the station.

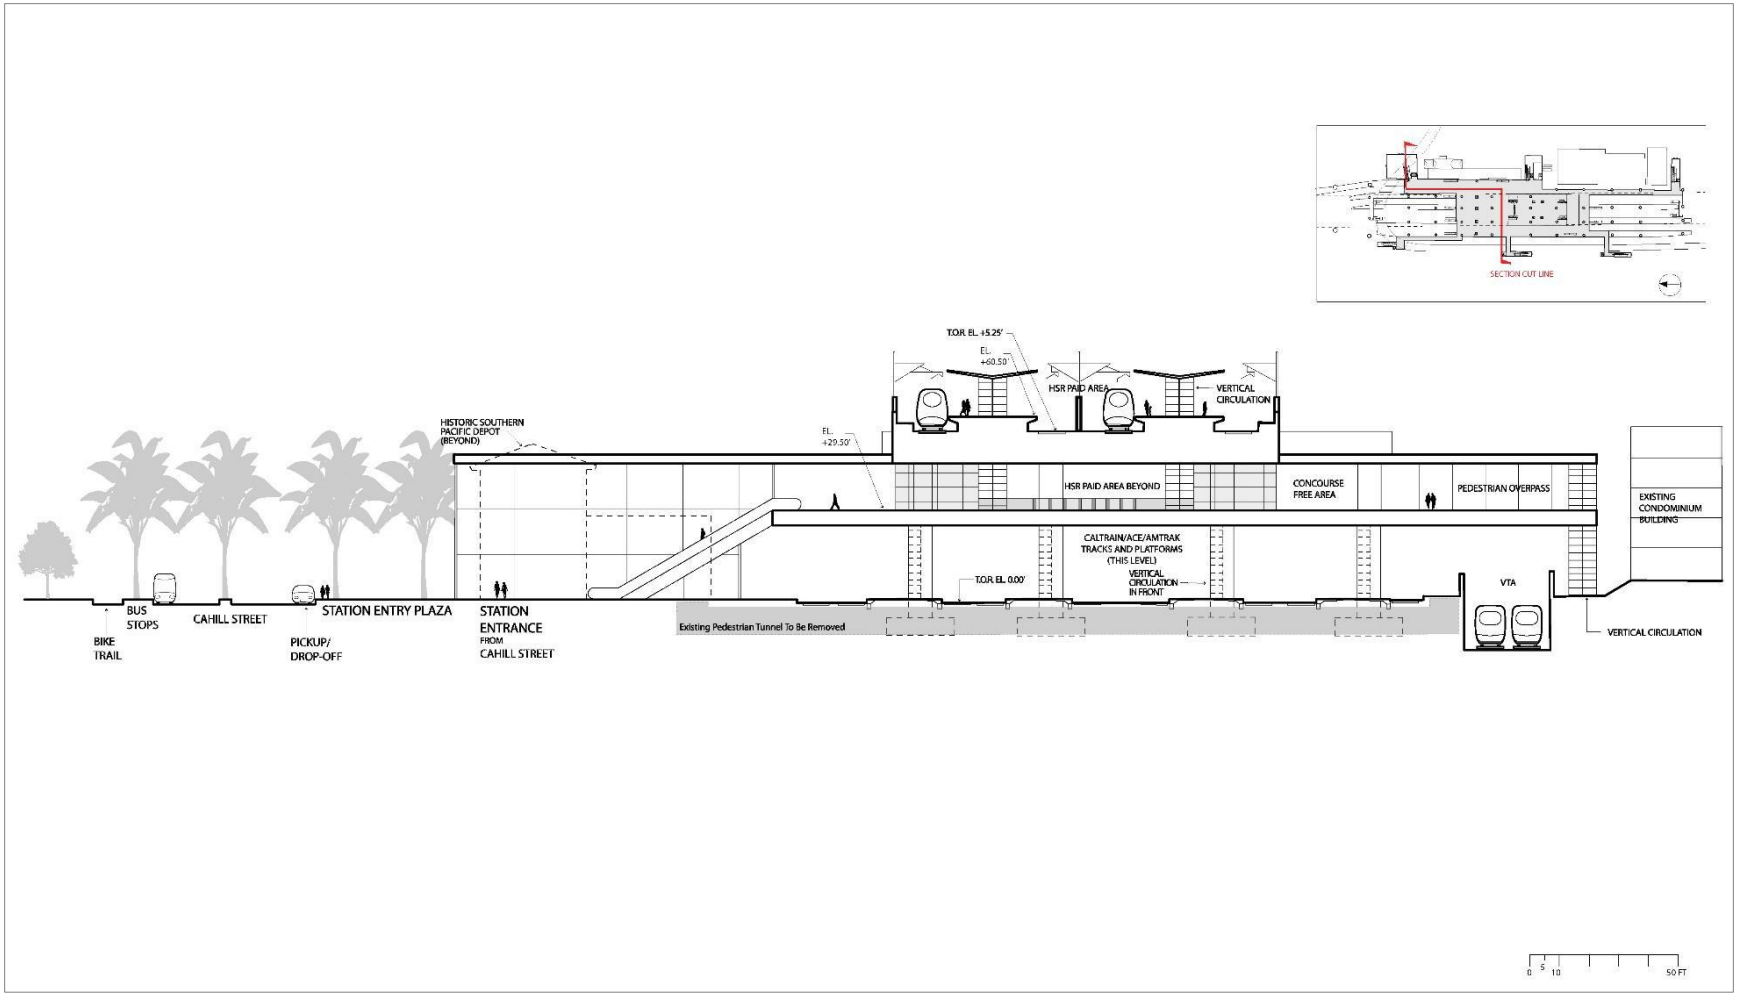
JUNE 2019

Figure 2-8 Conceptual Diridon Aerial Station Plan



Source: Authority 2019c

JUNE 2019

Figure 2-9 Conceptual San Jose Diridon Station Cross Section

The existing off-site bus transit center would be relocated to an on-street facility on Cahill, Stover, and Crandall Streets. Street improvements would include reconfiguring and extending Cahill Street from Santa Clara Street to Park Avenue, and converting Cahill, Stover, and Crandall Streets to a transit street with 12–15 bus stops. Montgomery Street would be reconfigured to provide curb space for a bus layover. A pick-up/drop-off zone of 1,900 square feet would be provided. New two-way cycle tracks would be installed on the east side of Cahill Street. A 4,000-square-foot bicycle facility would be constructed. New signals and pedestrian crossings would be developed at Cahill and Park, Otterson, Stover, West San Fernando, and Crandall Streets.

Other rail operators in the station area are Caltrain, Altamont Corridor Express, Amtrak, VTA light rail, and future BART. VTA has plans to construct new light rail station platforms as a separate project, and BART plans to extend service from the Berryessa Station to Santa Clara with a stop at Diridon by 2026. As a separate project, VTA has plans to construct new light rail station platforms.

Traction Power Sites and Power Connections

One new traction power substation (TPSS) would be constructed in this subsection on the east side of the Caltrain corridor south of I-880 in San Jose (just southeast of the I-880 overcrossing). The TPSS would be interconnected to two new gas-insulated substation breaker-and-a-half bays. The bays would be installed within the fenceline of the PG&E FMC substation, just north of the I-880 overcrossing, via an aerial double-circuit 115-kilovolt (kV) tie-line.

Train Control and Communication Facilities

An enhanced ATC system would control the trains and comply with the FRA-mandated positive train control requirements, including safe separation of trains, over-speed prevention, and work zone protection. This system would include communications towers at intervals of approximately 1.5–3 miles. Signaling and train control elements within the right-of-way would include 10- by 8-foot communications shelters that house signal relay components and microprocessor components, cabling to the field hardware and track, signals, and switch machines on the track. Communications towers in these facilities would use a 6- to 8-foot-diameter 100-foot-tall pole. The communications facilities would be located near track switches and would be grouped with other traction power, maintenance, station, and similar HSR facilities where possible. Where communications towers cannot be co-located with TPSSs or other HSR facilities, the communications facilities would be sited near the HSR corridor in a fenced area approximately 20 by 15 feet.

Under Alternative 1, there would be six ATC sites located between I-880 in San Jose and the I-280 and SR 87 interchange:

- Two sites near the TPSS facility
- One site just north of the San Jose Diridon Station
- Three sites between Park Avenue and the proposed HSR crossing of SR 87

One stand-alone communications radio site would be constructed, at one of two alternative locations, both south of Scott Boulevard along the east side of the Caltrain corridor.

Maintenance Facility

No maintenance facilities are proposed for this subsection.

2.2.1.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The Monterey Corridor Subsection would be approximately 9 miles long and entirely within the San Jose city limits. From the San Jose Diridon Station Approach Subsection at West Alma Avenue, just south of the Caltrain Tamien Station, the alignment would extend primarily southeast to Bernal Way (Figure 2-4). Alternative 1 would be on viaduct in the median of Monterey Road. UPRR MT1, Caltrain MT2, and Caltrain storage tracks would be shifted east between West Alma Avenue and Caltrain/UPRR control point (CP) Lick, at the southeast base of Communications Hill.

Railroad bridges over Almaden Road and Almaden Expressway would be extended to accommodate the track shift. The UPRR Luther spur track south of Almaden Expressway would also be relocated to accommodate the MT shifts.

From West Alma Avenue, the HSR alignment would descend from a viaduct 54 feet above grade to embankment (i.e., 5 feet or higher) north of Almaden Road. The alignment would continue primarily on embankment to cross over Almaden Road on a short aerial structure, then under Almaden Expressway, then continue south on embankment to at grade under Curtner Avenue. The alignment would continue south primarily at grade along the northern base of Communications Hill and ascend to aerial structure before crossing over and entering the Monterey Road median just south of Hillsdale Avenue. Construction of the viaduct over the existing Caltrain Capitol Station would require falsework over the station if constructed by cast-in-place methods or would require relocating the station 500 feet to the south if constructed by precast segments. The alignment would continue south on viaduct in the median of Monterey Road, crossing over Capitol Expressway, Skyway Drive, Branham Lane, Roeder Road/Chynoweth Avenue, Blossom Hill Highway, SR 85/West Valley Freeway, and Bernal Road.

The design assumes a reduction from six to four travel lanes on Monterey Road, beginning south of Southside Drive and continuing to a short distance south of Blossom Hill Road where the existing roadway is already four travel lanes. Three existing mid-block left-turn lanes would be closed because of substandard stopping sight distance. Additionally, the design assumes a combined left-turn and through lane at Palm Avenue.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Two traction power paralleling stations would be constructed in this subsection:

- North of the alignment near Curtner Avenue or south of the alignment at Communications Hill
- South of SR 85 or between Bernal Road and the Bernal Road ramp onto Monterey Road

Train Control and Communication Facilities

One ATC site would be constructed in the Monterey Corridor Subsection at one of two locations east of the guideway in the vicinity of Chynoweth Avenue.

Three stand-alone communications radio sites are proposed:

- Near Almaden Road on the east side of the Caltrain corridor (two site options)
- Near Capitol Expressway (two site options)

Maintenance Facility

No maintenance facilities are proposed for this subsection.

2.2.1.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection would be approximately 30 to 32 miles long and located south of the Monterey Corridor Subsection (Figure 2-5). From Bernal Way in South San Jose, the alignment would extend through Morgan Hill and San Martin to the Downtown Gilroy Station, then curve generally east across the Pajaro River floodplain and through a portion of northern San Benito County before entering a tunnel (Tunnel 1) at the base of the Diablo Range. The alignment would exit the tunnel at Casa de Fruta Parkway/SR 152 in unincorporated eastern Santa Clara County, where it would transition to the Pacheco Pass Subsection. Alternative 1 in this subsection

would construct the Viaduct to downtown Gilroy design option and an aerial Downtown Gilroy Station.

Beginning at the southern limit of the Monterey Corridor Subsection, the alignment would be on viaduct in the median of Monterey Road. In this four-lane section of the road, the design assumes a combined left-turn and through lane to Palm Avenue. The alignment would begin curving east on viaduct (approximately 40 feet above grade) near Ogier Avenue in Santa Clara County. The northbound lanes of Monterey Road would be realigned at this transition to cross beneath the HSR viaduct between columns of the aerial structure.

After crossing the Coyote Valley on viaduct, the alignment would cross over Burnett Avenue in Morgan Hill and parallel US 101 on the west side of the freeway. Continuing south, the alignment would bypass downtown Morgan Hill by crossing over Cochrane Road and associated freeway ramps, East Main Avenue, East Dunne Avenue and associated freeway ramps, and Tennant Avenue and associated freeway ramps.

South of Tennant Avenue and the city limits of Morgan Hill, the alignment would turn west, relocating the cul-de-sac at Fisher Avenue to the west of the HSR facility, then crossing over Maple Avenue, West Little Llagas Creek, East Middle Avenue, and Llagas Creek before rejoining Monterey Road and the UPRR corridor in the community of San Martin. The crossing of Llagas Creek would allow for wildlife movement by clear-spanning both banks and riparian habitat. New storm drainage infrastructure would be constructed on the west side of the alignment along Llagas Creek. The alignment would continue on viaduct along the east side of UPRR and cross over East San Martin Avenue.

South of Las Animas Avenue and the west branch of Llagas Creek, the alignment would curve east over Leavesley Road and Casey Lane. Continuing south, the viaduct would cross the Gilroy Prep School/South Valley Middle School sports field, a portion of the Gilroy Prep School campus, and Upper Miller Slough (with armor added to the channel to strengthen the stormwater conveyance) before crossing over IOOF Avenue, Lewis Street, Martin Street, East 6th Street, and a realigned East 7th Street, to arrive at the downtown Gilroy station on low viaduct (approximately 33 feet high).

South of the Downtown Gilroy Station, the alignment would continue on viaduct over East 10th Street l. Banes Lane would be reconstructed to provide a standard cul-de-sac. South of the Princevale Channel crossing, the alignment would ascend, still on viaduct, over Luchessa Avenue, US 101, and one spur UPRR track. After branching from the main UPRR track and crossing under the HSR viaduct, the new UPRR track for freight access to the MOWF would be provided to travel at grade on the east side of the new HSR track toward the South Gilroy MOWF site. Both the UPRR track and HSR tracks would cross the City of Gilroy wastewater disposal ponds. Continuing south, the alignment would ascend onto embankment. New storm drainage infrastructure would be constructed on the west side of the alignment at Carnadero Avenue, which would be closed where it meets the alignment. Bloomfield Avenue would be realigned to cross over the South Gilroy MOWF site. Sheldon Avenue would become a cul-de-sac south of the HSR alignment and would be abandoned north of the alignment. Before crossing the Pajaro River, the alignment would ascend onto viaduct.

The HSR alignment south and east of Gilroy would cross an agricultural area in Santa Clara and San Benito Counties that is part of the upper Pajaro River floodplain, historically referred to as Soap Lake. HSR guideway on viaduct would be built over the major watercourses to provide a floodplain crossing that is neutral to the hydrology and hydraulics of the floodplain and to accommodate wildlife movement. Because of the Calaveras fault crossing at this location, Tequisquita Slough would be partially filled by approximately 800 feet of HSR embankment. The embankment area would include cross-culverts and 1.3 acres of adjacent floodwater detention basins; in addition, an extended viaduct over Pacheco Creek would serve to maintain floodplain capacity and function. HSR would be on embankment between Pacheco Creek and Lovers Lane. The alignment would return to viaduct at Lovers Lane. After Lovers Lane, the alignment would continue in a combination of embankment and viaduct until reaching the portal for Tunnel 1 on the east side of SR 152.

After exiting the 1.4-mile Tunnel 1 on the west side of SR 152, the alignment would cross over SR 152 and the southern portion of the Pacheco Creek Valley on an aerial structure south of Casa de Fruta. The alignment would move onto embankment just beyond Southside Way at the western transition to the Pacheco Pass Subsection.

Wildlife Crossings

Three wildlife crossings would be provided at the base of Tulare Hill north of the Metcalf Substation connecting to Coyote Creek. The existing culvert under Monterey Road at Fisher Creek would be realigned and replaced with a larger box culvert to improve wildlife movement under Monterey Road and the HSR track. The crossing of Llagas Creek would allow for wildlife movement by clear-spanning both banks and riparian habitat. The alignment would be primarily on viaduct through the Soap Lake area to allow for wildlife movement. Viaducts have heights, widths and depths considered to be very favorable for wildlife movement.

Stations

Alternative 1 would enter the Downtown Gilroy Station on aerial structure (Figures 2-10 and 2-11). The HSR Downtown Gilroy Station would be constructed south of the existing Caltrain station. The station approach would be on a low viaduct—approximately 33 feet to top of rail—with dedicated HSR tracks to the east of UPRR between relocated Old Gilroy/7th Streets and 9th Street. The 800-foot platforms would be on the east and west side of the HSR tracks. The new HSR station building would have both east and west entrances: the main entrance for passengers arriving by auto or bicycle would be on the east side while the main entrance for passengers arriving on foot or by transit would be on the west side. The HSR station building would encompass 60,513 square feet with a 4,400-square-foot substation and systems building. The concourse would be below the new HSR tracks.

The existing 471 Caltrain parking spaces on the west side of the station would be replaced 1:1 by either reconfiguring parking on the west side of the station or relocating it to the east side of the station. The existing 269 San Ysidro housing development parking spaces would be replaced 1:1 with new surface parking at the south end of Alexander Street. HSR parking demand would be 970 spaces in 2040. In addition, the station site plan provides 970 new parking spaces in five areas, for a total of 1,710 parking spaces in 2040. One site would be west of the station along Monterey Road at 9th Street. The other four would be east of the station along Alexander Street at Old Gilroy Street, 9th Street, 10th Street, and Banes Lane. A multimodal access plan would be developed prior to design and construction of the station. The plan would be developed in coordination with local agencies and would include a parking strategy that would confirm the location, amount, and phasing of parking.

A total of eight bus bays would be provided. Street improvements would include realignment of Old Gilroy Street at East 7th Street; existing grade crossings would remain unchanged. A 4,000-square-foot bicycle facility would be constructed. Class II bike lanes would be provided on 7th and Alexander Streets.

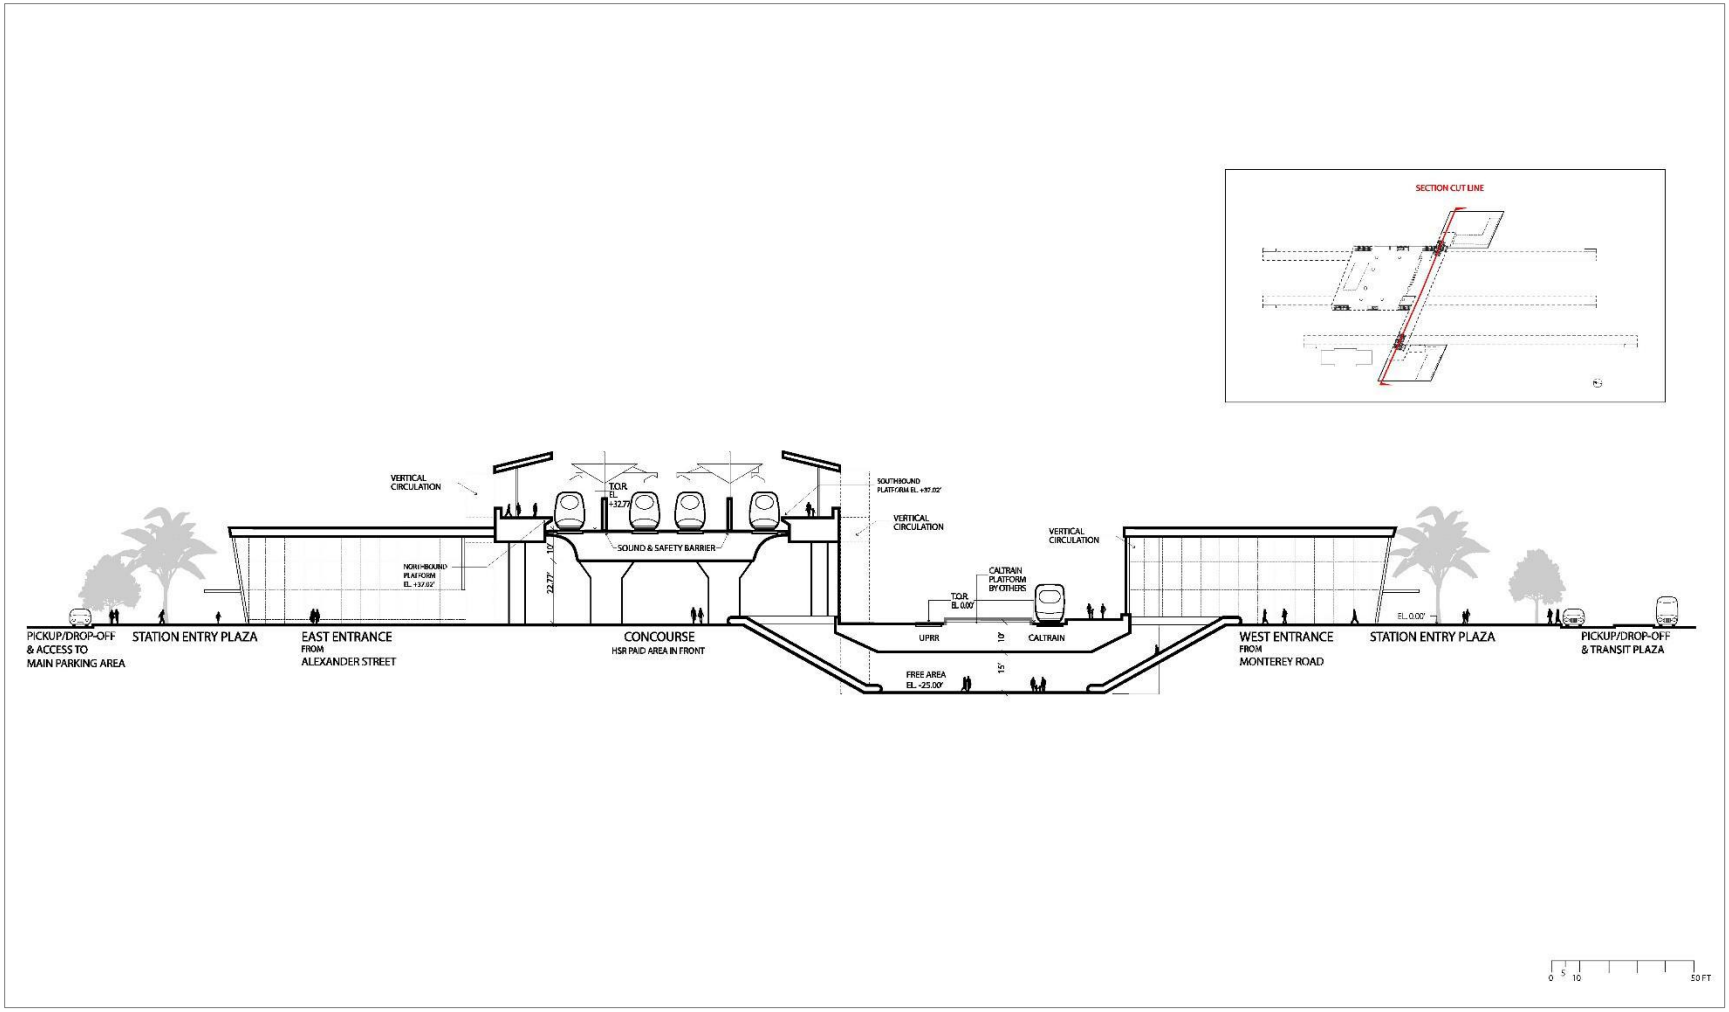
JUNE 2019

Figure 2-10 Conceptual Downtown Gilroy Aerial Station Plan



Source: Authority 2019c

JUNE 2019

Figure 2-11 Cross Section of Downtown Gilroy Station (Viaduct)

Traction Power Facilities

One new TPSS, Site 4—Gilroy, would be constructed at one of two alternate locations on the north side of the alignment: either east or west of Bloomfield Avenue. At this site, one new PG&E switching station would be co-located with the TPSS. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnections connecting the TPSS to a new utility switching station, to existing PG&E facilities, or both, typically within tie-line/utility corridors. North of Site 4—Gilroy, a traction power switching station would be constructed east of the HSR alignment at a location north of Palm Avenue.

Four traction power paralleling stations would be constructed adjacent to the guideway at the following locations:

- South of the alignment, either south of Diana Avenue or at the intersection of San Pedro Avenue and Walnut Grove Drive
- North of the alignment, either south of Masten Avenue or south of Rucker Avenue
- In the vicinity of Lovers Lane, either south of the alignment and west of Lovers Lane or north of the alignment and west of Lovers Lane
- At Tunnel 1 east portal

PG&E would reinforce the electric power distribution network to meet HSR traction and distribution power requirements by replacing (reconductoring) the 9.8-mile Metcalf to Morgan Hill and the 10.8-mile Morgan Hill to Llagas 115-kV power lines. The existing power lines to be reconductored, reusing the poles and towers, begin at the Metcalf Energy Center in San Jose and continue southeast parallel to the alignment on the east side before crossing to the west side near Ogier Avenue. Continuing on the west side to the Morgan Hill Substation on West Main Avenue in Morgan Hill, the lines then cross the east side of Peak Avenue and Dewitt Avenue, spanning West Dunne Avenue, Chargin Drive, Spring Avenue, and several residences. The alignment would continue south across an open-space area, then follow Sunnyside Avenue for approximately 0.5 mile. The alignment would continue south for approximately 4 miles, spanning additional open-space areas of wineries and the Corde Valle Golf Course. The alignment would then turn east along the north side of Day Road before heading south for approximately 2.5 miles and terminating at the Llagas Substation in Gilroy. Reconductoring at Metcalf Energy Center in San Jose would be required as well.

A permanent overhead distribution electrical power line from TPSS Site 4 to the Tunnel 1 portal location would provide power to the tunnel boring machine during construction and the tunnel fire-life-safety system during operation.

There are alternative sites for power drops at both portals for Tunnel 1. At each portal, one site is north of the alignment and one is south.

Train Control and Communication Facilities

A total of 17 ATC sites would be constructed in the Morgan Hill and Gilroy Subsection for this alternative:

- One site east of Monterey Road near Palm Avenue (two site options)
- One site at East Middle Avenue (two site options)
- One site between Las Animas Avenue and Leavesley Road
- One site south of Leavesley Road
- One site south of Lewis Street
- One site north of 6th Street in Gilroy
- Two sites south of 6th Street in Gilroy
- Two sites north of 10th Street in Gilroy
- One site south of Banes Lane
- Five sites north of Carnadero Avenue

- Three sites east of the Pajaro River
- One site near Lake Road (two site options)

Six stand-alone communication radio sites would be constructed within this subsection:

- Forsum Road or Blanchard Road (two site options)
- Near Bailey Avenue (two site options)
- Between Barnhart Avenue and Kirby Avenue (two site options)
- South of Cochrane Road along US 101 (two site options)
- North of Cox Avenue and south of West San Martin Avenue (two site options)
- East of the Pajaro River, south of Gilroy

Maintenance Facilities

The MOWF under Alternative 1 would be located in South Gilroy between Carnadero Road and Bloomfield Avenue (Figure 2-12) to accommodate machinery and inspection and maintenance staff. The MOWF would cover approximately 75 acres. The freight connection would be provided as described above.

2.2.1.4 Pacheco Pass Subsection

Alignment and Ancillary Features

The Pacheco Pass Subsection would be approximately 25 miles long. The alignment would generally follow the existing SR 152 corridor east from Casa de Fruta for approximately 17 miles, then diverge north around the Cottonwood Creek ravine of the San Luis Reservoir for approximately 8 miles before transitioning to the San Joaquin Valley Subsection near I-5 (Figure 2-6). Tunnel is the only design option in this subsection.

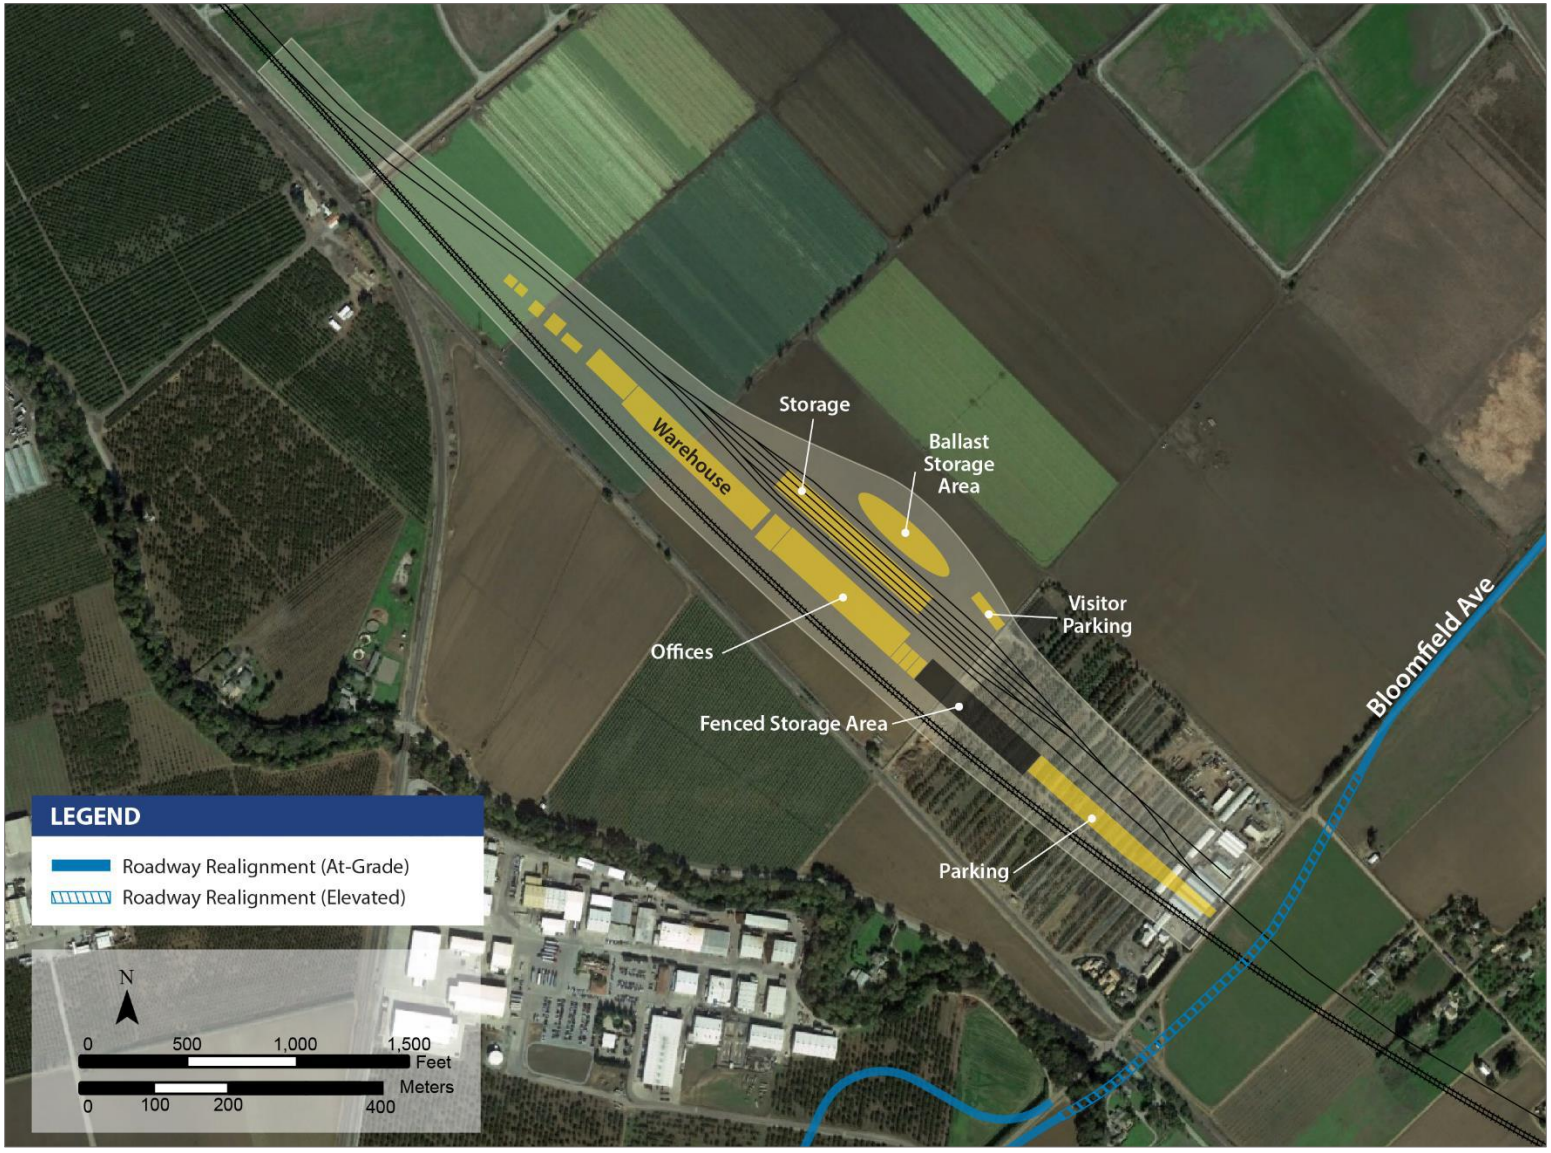
From the eastern limit of the Morgan Hill and Gilroy Subsection, the guideway would transition from aerial structure to embankment along the southern boundary of Casa de Fruta. This stretch of embankment would be on fill or in excavated hillside cuts to accommodate a level HSR guideway profile over varied surface elevations and to control unstable slopes known for vulnerability to landslip (i.e., areas subject to the downward falling or sliding of a mass of soil, detritus, or rock on or from a steep slope). The alignment would ascend to viaduct over Pacheco Creek along the south side of SR 152 and remain on viaduct to the Tunnel 2 portal. This portal would include a staging area for tunnel construction and a permanent area for traction and facility power with access provided by a service road from SR 152. Tunnel 2 would extend northeast approximately 13.5 miles. Access to the Tunnel 2 east portal for HSR construction, operations, and maintenance would be on McCabe Road north of Romero Ranch. Continuing east, the HSR guideway would be predominantly on a combination of embankment and aerial structures, with viaducts over Romero Creek and the California Aqueduct. Romero Road would be realigned at its intersection with I-5. East of I-5, the alignment would cross over SR 33/Santa Nella Road and the CCID Outside Canal before transitioning to the San Joaquin Valley Subsection at Fahey Road.

Wildlife Crossings

Four wildlife crossing culverts would be provided west of the California Aqueduct, with an additional two wildlife crossings between the California Aqueduct and the Delta-Mendota Canal and one between the Delta-Mendota Canal and I-5. Three wildlife crossings would be provided between I-5 and Santa Nella Road, and three more between Santa Nella Road and Fahey Road. Viaducts would also function as wildlife movement areas in this subsection.

Stations

No new HSR stations are proposed for this subsection.



Source: Authority 2019c

JUNE 2019

Figure 2-12 South Gilroy Maintenance of Way Facility

Traction Power Facilities

One new TPSS, Site 5—O'Neill, would be constructed approximately 1.2 miles west of the Calfornia Aqueduct. A new 230-kV double-circuit tie-line would be constructed from the expanded Quinto switching station to the TPSS, paralleling an existing PG&E transmission line for approximately 0.6 mile. The tie-line would be installed either underground in a utility easement or overhead, requiring the existing 500-kV transmission line to be raised. No reinforcements to the PG&E power system would be required for this site. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnection. The interconnection would link the TPSS to a new PG&E switching station, to existing PG&E facilities, or both—typically within tie-line/utility corridors.

A traction power switching station would be constructed at each Tunnel 2 portal. A power drop site would be co-located with the switching stations. A new permanent distribution power line from the Quinto switching station along McCabe Road to the Tunnel 2 east portal location would provide power for tunnel construction and fire and life safety systems during operations. The existing PG&E 230-kV Quinto switching station would be expanded within the fence line to support the HSR system.

Traction power paralleling stations would be constructed at three locations:

- Two stations within Tunnel 2 cross passages, approximately 5 miles apart
- One station located either southeast or northwest of the alignment crossing of Fahey Road

Train Control and Communication Facilities

Three ATC sites would be constructed in the Pacheco Pass Subsection at the following locations:

- West portal of Tunnel 2
- Underground within the limits of Tunnel 2
- Adjacent to TPSS Site 5

One stand-alone communications radio antenna site would be constructed in the Pacheco Pass Subsection:

- Near SR 152 and the Tunnel 2 west portal
- 1 mile west of Tunnel 2
- Delta-Mendota Canal crossing

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.1.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

The San Joaquin Valley Subsection would be approximately 18 miles long, from east of I-5 (at Fahey Road) to the intersection of Henry Miller Road and Carlucci Road in Merced County, where the alignment would connect to the Central Valley Wye (Figure 2-7). The single design option in this subsection is a combination of viaduct and embankment along Henry Miller Road, identified as the Henry Miller Road design option.

South of Fahey Road, the guideway would continue east and cross over three irrigation ditches, Cherokee Road, the CCID Main Canal, two additional irrigation ditches, and adjacent farmland on viaduct. Continuing east, the alignment would be on embankment (including four proposed culvert crossings for irrigation ditches) before ascending on an approximately 1.4-mile-long viaduct over the San Luis (Volta) Wasteway, the UPRR West Side branch line, and Ingomar Grade Road.

The alignment would descend to embankment west of Volta Road while turning southeast before crossing to the south side of Henry Miller Road. Henry Miller Road would be realigned to pass over the HSR alignment on a bridge. The HSR embankment between the Volta Road

overcrossing and Los Banos Creek would cross over two proposed culverts to maintain irrigation canals. The alignment would then ascend to cross over Los Banos Creek and Badger Flat Road on a 0.8-mile-long viaduct before descending onto embankment.

The alignment would continue east for 3.6 miles on embankment, over several combined wildlife crossing/drainage culverts and drainage culverts, including an irrigation ditch at Wilson Road, an irrigation ditch at Johnson Road, two irrigation ditches at Nantes Avenue, the Santa Fe Canal, the San Luis Canal, the San Luis Drain, and the Porter-Blake Bypass. A road would be constructed between Badger Flat Road and Nantes Avenue. SR 165/Mercey Springs Road would be raised to cross over the HSR alignment and Henry Miller Road on a bridge. East of SR 165 and the Santa Fe Grade, the alignment would ascend to an approximately 1.8-mile viaduct south of the Los Banos State Wildlife Area across Mud Slough to maintain wildlife movement within the Grasslands Ecological Area (GEA). Baker Road, Midway Road, and Hereford/Salt Slough would be closed south of Henry Miller Road. Box Car Road would become a cul-de-sac with a new road to the east. Hutchins Road would be abandoned. The alignment would continue on embankment to the eastern limit of the subsection and the project. Culvert crossings would be provided for the San Pedro Canal, Boundary Drain, Lone Tree Canal, Devon Drain, West Delta Drain, West Delta Canal, Dambrosia Ditch, Delta Canal and seepage drain, East Delta Canal, Poso Drain, Belmont Drain, Delta Canal #1, West San Juan Drain, San Juan #1, and several other irrigation ditches and drains in the section of viaduct over the GEA. Several local roadways—Delta Road, Turner Island Road, and Carlucci Road—would be elevated over the HSR guideway, maintaining access to adjacent properties. The alignment would transition to the Central Valley Wye at Carlucci Road.

Wildlife Crossings

The rail alignment would be primarily on viaduct where it overlaps with the GEA boundary and modeled wildlife movement corridors. Three additional wildlife crossing culverts would be added between Fahey Road and Cherokee Road. Regularly spaced wildlife crossing culverts would be provided through the remainder of this subsection. In total, there would be 64 wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

A traction power switching station would be constructed on the north or south side of the alignment at one of two alternate sites east of the intersection of Henry Miller Road and Santa Fe Grade. Traction power paralleling stations would be constructed at the following locations:

- Either east or west of the Henry Miller Road overcrossing of the HSR alignment near Volta Road (two site options)
- Intersection of Henry Miller Road and Box Car Road (two site options either north or south of the alignment)

Train Control and Communication Facilities

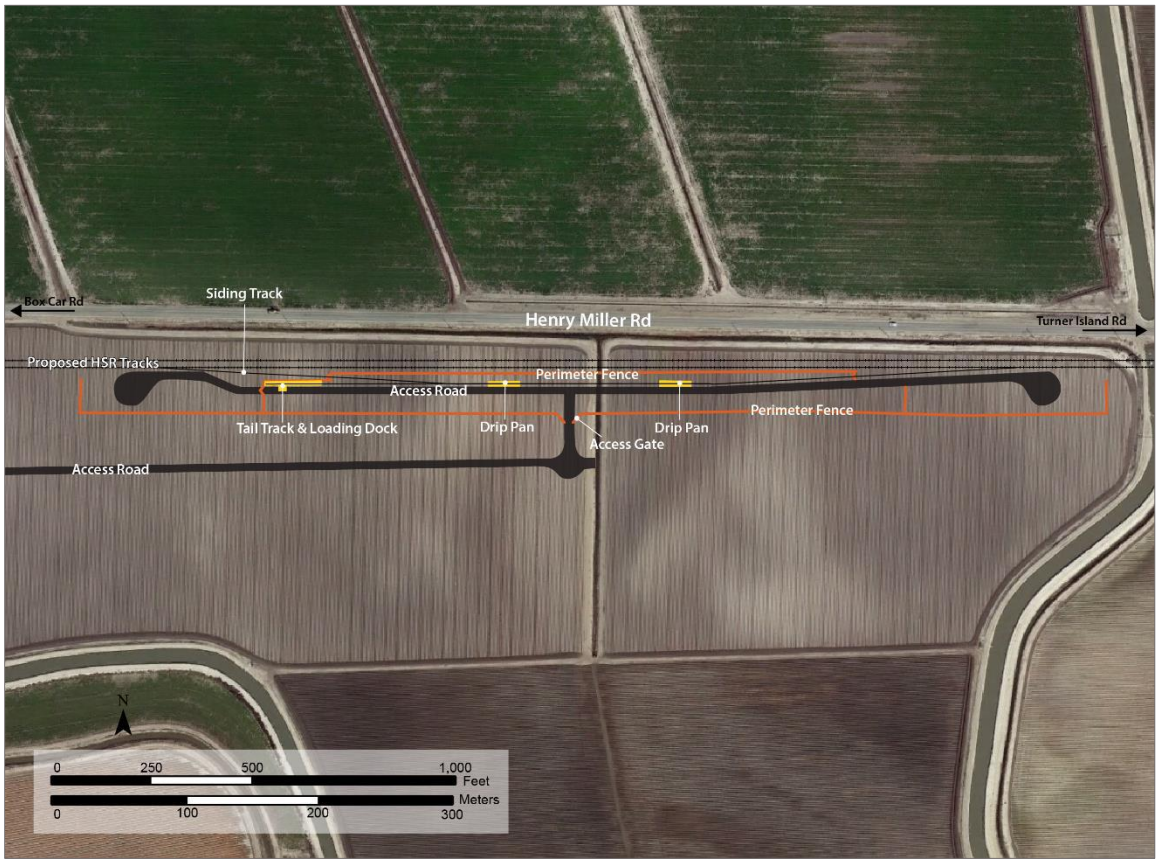
Four ATC sites would be constructed in the San Joaquin Valley Subsection:

- One site east of the CCID Main Canal (two options)
- Three sites near Johnson Road
- One site near Box Car Road (two site options)

One stand-alone communication radio site would be constructed: at Wilson Road (two site options): east of the San Pedro Canal and at Carlucci Road.

Maintenance Facility

An MOWS is proposed near Turner Island Road near the eastern limit of the project (Figure 2-13). The MOWS would be about 0.5 mile long, encompassing about 4 acres. The facility would be constructed near Henry Miller Road to avoid the GEA and other sensitive habitat.



Source: Authority 2019c JUNE 2019

Figure 2-13 Maintenance of Way Siding near Turner Island Road

2.2.2 Alternative 2

Alternative 2 is the alternative that most closely approximates the alignment and structure types identified in the prior program-level documents, implemented by limiting longitudinal encroachment into the UPRR right-of-way to combine railroad grade separations with minimum property displacements. The HSR guideway under this alternative would be comprised of 20.9 miles on viaduct, 8.5 miles at grade, 41.0 miles on embankment, two tunnels totaling 15.0 miles, and 3.2 miles in trench.

2.2.2.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

Alternative 2 would begin at Scott Boulevard at grade in blended service with Caltrain. Approximately 300 feet south of Scott Boulevard, the HSR tracks would separate from the Caltrain tracks and begin ascending to embankment and then to the 50-foot-tall dedicated viaduct at Main Street. The long viaduct under Alternative 2 would have a wider footprint than the short viaduct to I-880 under Alternative 1, requiring more curve straightening of the Caltrain tracks north of I-880. At the Lafayette Street crossing, the project would replace the existing pedestrian

overpass with an underpass. The existing De La Cruz Boulevard overcrossing would be replaced with an undercrossing to enable the HSR aerial structure to cross 43 feet high over De La Cruz Boulevard, the relocated UPRR MT1 and two industry tracks, and the Caltrain Santa Clara Station. The Santa Clara Station northbound platform would be reconstructed to accommodate the supports for the HSR aerial structure. South of Santa Clara Station, the three relocated UPRR tracks would cross under the HSR viaduct so that all Caltrain and UPRR tracks would be west of the HSR viaduct. The HSR viaduct would then ascend to 68 feet to cross over I-880.

Farther south, the existing West Hedding Street roadway overcrossing would be replaced by an undercrossing under the rail corridor. A short section of retained fill would be used to support the tracks over the future BART to San Jose tunnel. The intersection of Stockton Avenue and University Avenue would be replaced by cul-de-sacs; Emory Street would be a new cul-de-sac on the north side of HSR. The curve from westbound West Taylor Street to northbound Chestnut Street would be realigned for the HSR crossing over West Taylor Street; the alignment would then ascend on a viaduct to cross over Cinnabar Street. The UPRR Warm Springs Subdivision Lenzen Wye would be relocated to the southwest. North Montgomery Street would be extended to Cinnabar Street to maintain property access beneath the 68-foot-high HSR viaduct. The alignment would curve west toward the UPRR/Caltrain MTs before crossing over the western part of the SAP Center parking lot, then over West Santa Clara Street to enter the new dedicated HSR aerial platforms at the San Jose Diridon Station.

Between San Jose Diridon Station and West Alma Avenue, Alternative 2 would be identical to Alternative 1. Continuing on an aerial structure, the alignment would diverge from the Caltrain right-of-way south of the San Jose Diridon Station HSR platforms by turning sharply east at the Park Avenue undercrossing of UPRR/Caltrain tracks. The HSR aerial structure would cross over Los Gatos Creek and San Carlos Street, then over Royal Avenue and the intersection of Bird Avenue and Auzerais Avenue, then over the I-280/SR 87 interchange. Continuing south along the east side of SR 87, the HSR aerial structure would cross over West Virginia Street and the Guadalupe River Trail, then over the Caltrain rail bridge, the Guadalupe River, and Willow Street. The HSR aerial structure would continue south over the Caltrain Tamien Station on an alignment between Tamien Station and the SR 87 freeway, transitioning to the Monterey Corridor Subsection at West Alma Avenue.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

The San Jose Diridon Station would be the same as described for Alternative 1.

Traction Power Facilities

One new TPSS would be constructed on the east side of the Caltrain corridor south of I-880 as described for Alternative 1.

Train Control and Communication Facilities

Alternative 2 would have six ATC sites within this subsection:

- One site at Scott Boulevard
- One site at Main Street
- One site just north of the San Jose Diridon Station
- Three sites between Park Avenue and the proposed HSR crossing of SR 87 (same as under Alternative 1)

No stand-alone communications radio sites would be built in this subsection under Alternative 2.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.2.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The Monterey Corridor Subsection is approximately 9 miles long and entirely within the San Jose city limits. However, Alternative 2 would begin the viaduct transition to the Monterey Road/UPRR corridor approximately 400 feet north of the transition under Alternatives 1 and 3 but would be primarily at grade or on embankment upon entering the road/rail corridor. Alterations of existing railroad track and systems between West Alma Avenue and CP Lick (near the east base of Communications Hill) would be the same as under Alternatives 1 and 3, except for a new, continuous intrusion barrier between the existing UPRR tracks and HSR tracks.

From West Alma Avenue, the HSR alignment would descend from a viaduct 54 feet above grade to embankment north of Almaden Road. The alignment would continue primarily on embankment on the west side of the Caltrain/UPRR tracks, crossing over Almaden Road on a short aerial structure, then proceeding at grade under West Almaden Expressway and Curtner Avenue. South of Curtner Avenue, the alignment would continue south at grade along the west side of the Caltrain/UPRR tracks around the northern base of Communications Hill, ascending to aerial structure before crossing over and entering the Monterey Road/UPRR corridor just south of Hillsdale Avenue. On the approach to Monterey Road, the aerial structure would cross over the UPRR tracks and the Caltrain Capitol Station while curving southeast to return to grade within the road/rail corridor northwest of the Capitol Expressway. Monterey Road would be realigned to the east, while HSR would run along the east side of UPRR. South of Fehren Drive, Monterey Road would be reduced from six to four lanes. Continuing south, the alignment would descend into trench beneath a widened Capitol Expressway bridge before ascending to grade at Skyway Drive. Under Skyway Drive Variant A, Monterey Road would retain its current at-grade configuration, and a new connector ramp located northwest of the intersection of Skyway Drive and Monterey Road would connect Monterey Road to the depressed Skyway Drive underpass. San Jose Fire Station #18 would have access along the connector ramp. Skyway Drive Variant B would depress Monterey Road to connect to the Skyway Drive underpass. Under this variant, access to the mobile home park northwest of the intersection of Skyway Drive and Monterey Road would be provided by a driveway across the northern portion of the San Jose South Service Yard property. Variant B would not provide access to the fire station.

Continuing south, the HSR alignment would be at grade or on embankment between Monterey Road and UPRR for the remainder of the subsection. Branham Lane and Roeder Road/Chynoweth Avenue would be lowered to be separated from the HSR and existing railroad crossings. Because of the new grade difference between Branham Lane and Roeder Road/Chynoweth, access to Rice Way and four driveways from Monterey Road would be closed. A new Branham Lane pedestrian bridge would span the combined railroad and Monterey Road corridor. The westbound Blossom Hill Road ramp at Monterey Road would be shifted to the east side of Monterey Road. A new pedestrian bridge would be built to maintain connectivity between Ford Road and the Caltrain Blossom Hill Station. The alignment would continue south at grade under SR 85/West Valley Freeway, with modifications to the existing highway bridge to allow HSR to pass underneath. The alignment would then cross under Bernal Road before transitioning to the Morgan Hill and Gilroy Subsection at Bernal Way.

Like the other alternatives, the design assumes a reduction from six to four travel lanes on Monterey Road, beginning north of Capitol Expressway and continuing to just south of Blossom Hill Road, where the existing roadway is already four travel lanes. Under Alternative 2, one left turn lane would be removed south of Senter Street and one left turn lane would be removed south of Roeder where Monterey Road would be depressed and grade separated from adjacent properties. Existing mid-block left-turn lanes would be closed because of substandard stopping sight distance. Alternative 2 (and Alternative 4) differs from Alternatives 1 and 3 by shifting all Monterey Road travel lanes and median to the east of their current locations.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

In the Monterey Corridor Subsection, traction power stations would be in the same area under Alternatives 1, 2 and 3. Traction power paralleling stations would be constructed at the following locations:

- Either the north side of the alignment near Curtner Avenue or the south side of the alignment at Communications Hill (same as Alternative 1)
- Either the south side of SR 85 or between Bernal Road and the Bernal Road ramp onto Monterey Road

Train Control and Communication Facilities

Train control and communication facilities under Alternative 2 would be the same as described for Alternative 1.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.2.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection under Alternative 2 would be approximately 31 miles long and located south of the Monterey Corridor Subsection. From Bernal Way in South San Jose, the alignment would extend through Morgan Hill and San Martin to the Downtown Gilroy Station, then curve generally eastward across the Pajaro River floodplain and through a portion of northern San Benito County before entering a tunnel (Tunnel 1) at the base of the Diablo Range. The alignment would exit the tunnel at Casa de Fruta Parkway/SR 152 in unincorporated eastern Santa Clara County, and then transition to the Pacheco Pass Subsection (Figure 2-8).

Continuing from the southern limit of the Monterey Corridor Subsection, Alternative 2 would be at grade on retained fill between the UPRR right-of-way and Monterey Road in South San Jose. Due to the proximity of the alignment to UPRR, a 3-foot-thick continuous intrusion barrier would be constructed between the proposed HSR and UPRR tracks. In contrast to the other alternatives, Alternative 2 would require the construction of new roadway grade separations to maintain east-west connectivity across the Monterey Corridor. Before turning south near Kittery Court, the two UPRR tracks would be realigned to the west to accommodate the alignment curvature required for HSR operations until returning to the existing alignment adjacent to the south side of the Calpine Metcalf Energy Center. The existing Fisher Creek culvert would be improved with a new culvert installed beneath the new HSR alignment and realigned Monterey Road and UPRR. The creek crossing would be improved to provide a suitable wildlife crossing. The Blanchard Road grade crossing would be closed.

As the UPRR and Monterey Road rights-of-way converge to the south approaching Bailey Avenue, the four-lane Monterey Road would be realigned eastward to accommodate the HSR alignment at grade between the railroad and roadway. The existing Bailey Avenue bridge would remain in place and HSR would cross beneath the road. The alignment would continue south, ascending onto embankment, crossing beneath a new Palm Avenue bridge and a new Live Oak Avenue bridge (which would also cross over UPRR, eliminating both existing at-grade crossings). Tilton Avenue would become a cul-de-sac. Madrone Parkway would be lowered to allow HSR and UPRR to cross over the roadway. At Cochrane Road, the realigned Monterey Road would converge with the existing roadway alignment.

As the alignment proceeds south along the UPRR alignment through Morgan Hill, a new culvert would be placed in the HSR embankment for Fisher Creek. The alignment would then cross over Monterey Road on a clear-span bridge. Continuing south on embankment along the east side of

UPRR, the HSR and UPRR alignments would cross over Main, East/West Dunne, San Pedro, and Tennant Avenues on short bridges over the roadways, which would be lowered 17–30 feet below grade to maintain east-west connections. A new pedestrian underpass would be provided to maintain access from east of the HSR corridor to the Morgan Hill Caltrain Station. Railroad Avenue would be closed between San Pedro Avenue and Barrett Avenue and relocated eastward between Barrett Avenue and Maple Avenue to accommodate the HSR alignment adjacent to UPRR. The existing bridge at Butterfield Boulevard would be extended to cross over the realigned Railroad Avenue and at-grade HSR alignment. The Butterfield Canal would be relocated to the east to accommodate the HSR alignment adjacent to UPRR.

Continuing south, the alignment would ascend onto embankment, and West Little Llagas Creek would flow through a new culvert. The existing East Middle Avenue would become cul-de-sacs on both sides of the alignment. A new alignment of East Middle Avenue would be constructed to the south, where it would cross over the HSR tracks and Monterey Road on a bridge. Monterey Road and UPRR would be realigned westward between East Middle Avenue and Roosevelt Avenue to accommodate the southward alignment curvature required for HSR operations. The realigned roadway and UPRR and the new HSR alignment would cross Llagas Creek on new clear-span bridges. South of Llagas Creek, Monterey Road would return to the existing alignment near Roosevelt Avenue.

San Martin Avenue would be realigned between Murphy and Harding Avenues to connect to Oak Street at Llagas Avenue (north of the HSR alignment) in San Martin. HSR would cross over San Martin Avenue and Oak Street, which would be below grade. A pedestrian path under the HSR embankment would be provided south to San Martin Avenue. Depot Street, UPRR, and Monterey Road, which parallel the HSR tracks at Oak Street, would cross the newly depressed San Martin (formerly Oak) Street on bridges supported by retained fill. HSR would continue south at grade adjacent to the east side of UPRR. Church Avenue would be raised onto a bridge over both HSR and UPRR. Fitzgerald and Masten Avenues would be realigned to the south and would be depressed beneath Monterey Road, UPRR, and HSR. Similarly, Rucker Avenue and Buena Vista Avenue would be depressed beneath Monterey Road, UPRR, and HSR. Both Cohansey Avenue and Las Animas Avenue would remain at grade with bridges for HSR and UPRR to cross over the existing streets.

Continuing south into Gilroy, the alignment would shift east for the approach to the Downtown Gilroy HSR Station. The existing culvert for the West Branch of Llagas Creek would be extended to the east to accommodate the rail alignment shift. HSR and UPRR would be on embankment (approximately 15–25 feet high) and cross over Leavesley Road, Casey Street, IOOF Avenue, Lewis Street, East 6th Street, and the realigned East 7th Street/Old Gilroy on bridges before arriving at the Downtown Gilroy Station embankment (approximately 16 feet high). East 7th Street and Old Gilroy would be realigned (as under Alternative 1). Each of these streets would be lowered approximately 20 feet beneath existing grade, and a pedestrian underpass would replace Martin Street across the rail alignment. Miller Slough would be realigned eastward in a new culvert beneath the railroad alignment. HSR and UPRR would continue on embankment, crossing over East 9th Street and East 10th Street.

The HSR alignment would continue on embankment south from the Downtown Gilroy Station to the Princevale Channel, then descend into a trench under Luchessa Avenue and US 101, where existing bridges would be demolished and reconstructed to accommodate the freeway undercrossing, and two UPRR spur tracks. Just south of the US 101 overcrossing, a freight connection would be made from UPRR on the south side of HSR, crossing over the HSR trench to connect to the South Gilroy MOWF on the north side of HSR. Two UPRR spur tracks would be realigned to connect to the MOWF freight track north of HSR.

The remainder of this subsection—to Casa de Fruta—would be the same as under Alternative 1.

Wildlife Crossings

Three adjacent box culverts would be installed to provide wildlife with a connection between Tulare Hill and Coyote Creek south of Metcalf Road. The box culverts under Monterey Road and

UPRR would be replaced with larger box culverts at Fisher Creek. HSR would also be on a box culvert over Fisher Creek. These three box culverts would have larger openings than existing culverts to improve wildlife movement. There would be seven additional crossings at Emado Avenue, Laguna Avenue, Richmond Avenue, Fox Lane, Paquita Espana Court, south of Palm Avenue, and south of Live Oak Avenue.

Stations

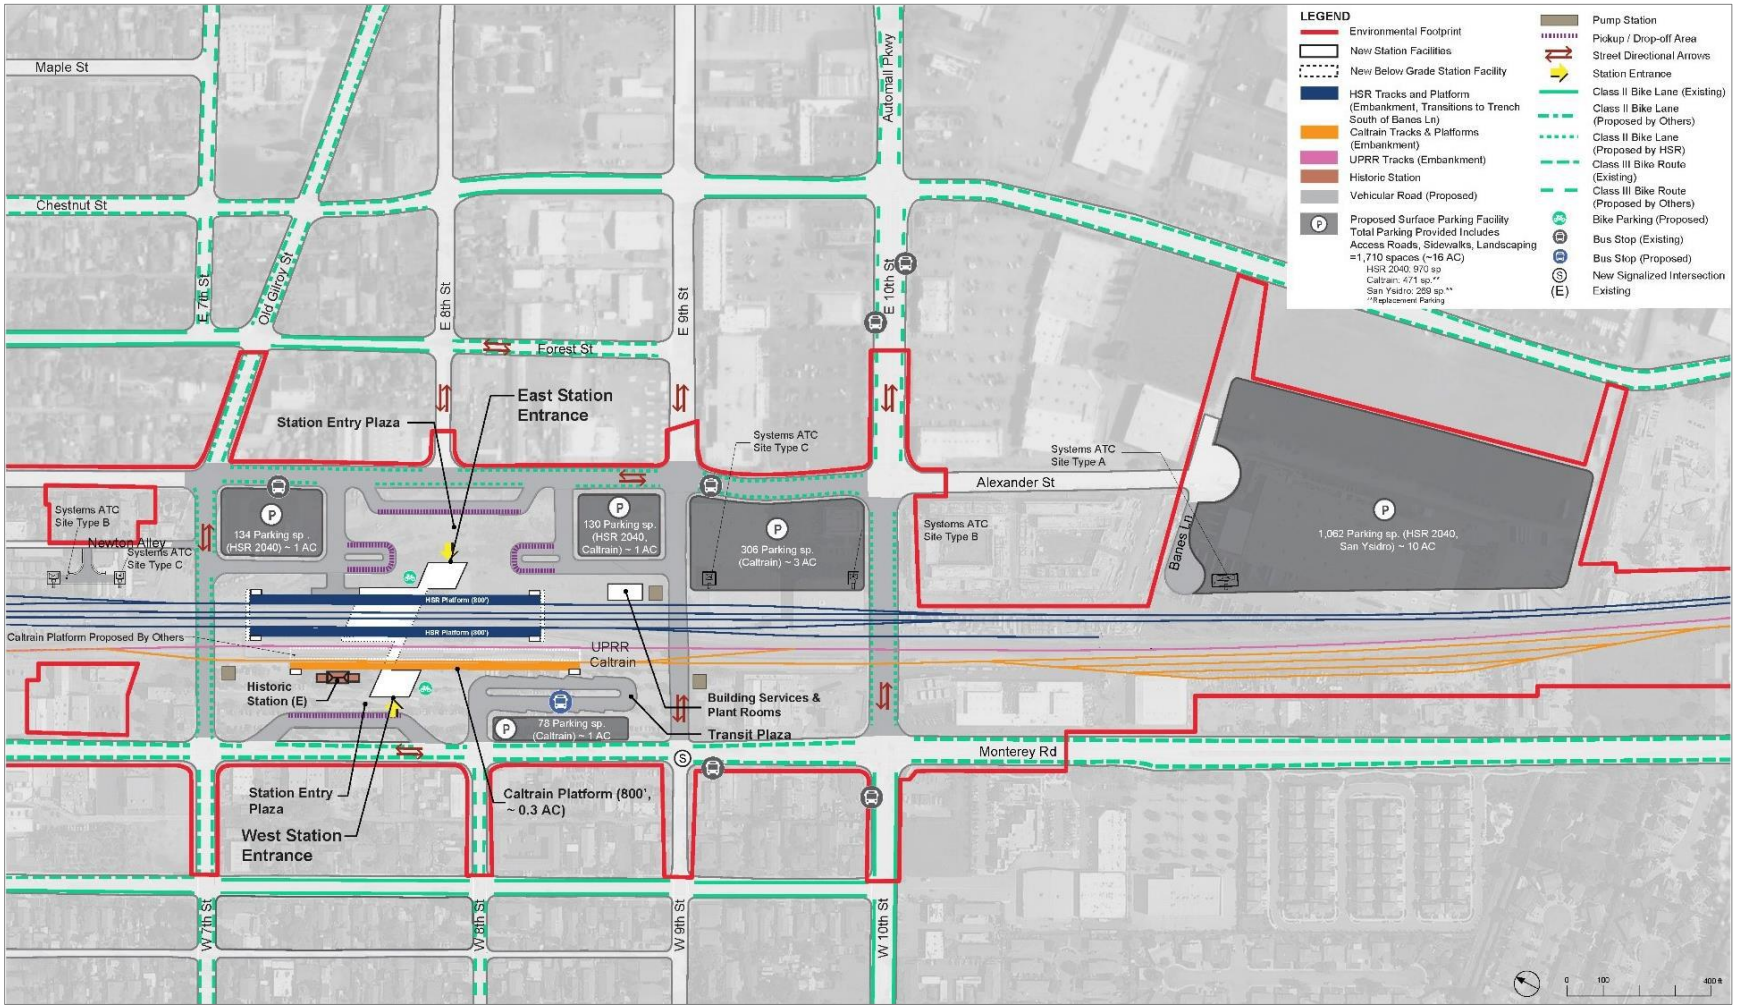
Alternative 2 would enter the Downtown Gilroy Station on embankment (Figures 2-14 and 2-15). The station layout and configuration would be similar to that described for Alternative 1, except that UPRR and Caltrain would be elevated to the same height as HSR on the embankment. The embankment station would also lower East 7th/Old Gilroy Street, East 9th Street, and East 10th Street by approximately 16 feet to maintain street access.

As under Alternative 1, the existing 471 Caltrain parking spaces on the west side of the station would be replaced 1:1 by either reconfiguring parking on the west side of the station or relocating it to the east side of the station. The existing 269 San Ysidro housing development parking spaces would be replaced 1:1 with new surface parking along Automall Parkway with access from the south end of Alexander Street. HSR would provide an additional 970 spaces in 2040, for a total of 1,710 parking spaces in 2040 (including existing demand). The station site plan provides 970 new parking spaces in five areas. One site would be located west of the station along Monterey Road at 9th Street. The other four would be on the east side of the station along Alexander Street at Old Gilroy Street, 9th Street, 10th Street, and Banes Lane. A multimodal access plan that includes a parking strategy would be developed in coordination with local agencies prior to design and construction of the station. A total of eight bus bays would be provided. Street improvements would include realignment of Old Gilroy Street at East 7th Street; existing grade crossings would remain unchanged. A 4,000-square-foot bicycle facility would be constructed. Class II bike lanes would be provided on 7th, Alexander, and 10th Streets.

Traction Power Facilities

As under Alternative 1, one new TPSS, Site 4—Gilroy, would be constructed at one of two alternate sites on the north side of the alignment: either east or west of Bloomfield Avenue. At this location, one new utility switching station would be co-located with the TPSS. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnection of the TPSS to a new utility switching station or to existing PG&E facilities, typically within tie-line/utility corridors. Site 4—Gilroy would connect to the Llagas PG&E substation via existing and proposed transmission or distribution lines along SR 152, Frazier Lake Road, and Bloomfield Avenue. Fiber optic and high-voltage lines would be reconductored overhead on existing towers where available. Where no overhead connections exist, both fiber optic and high-voltage lines would be undergrounded within or adjacent to the public right-of-way.

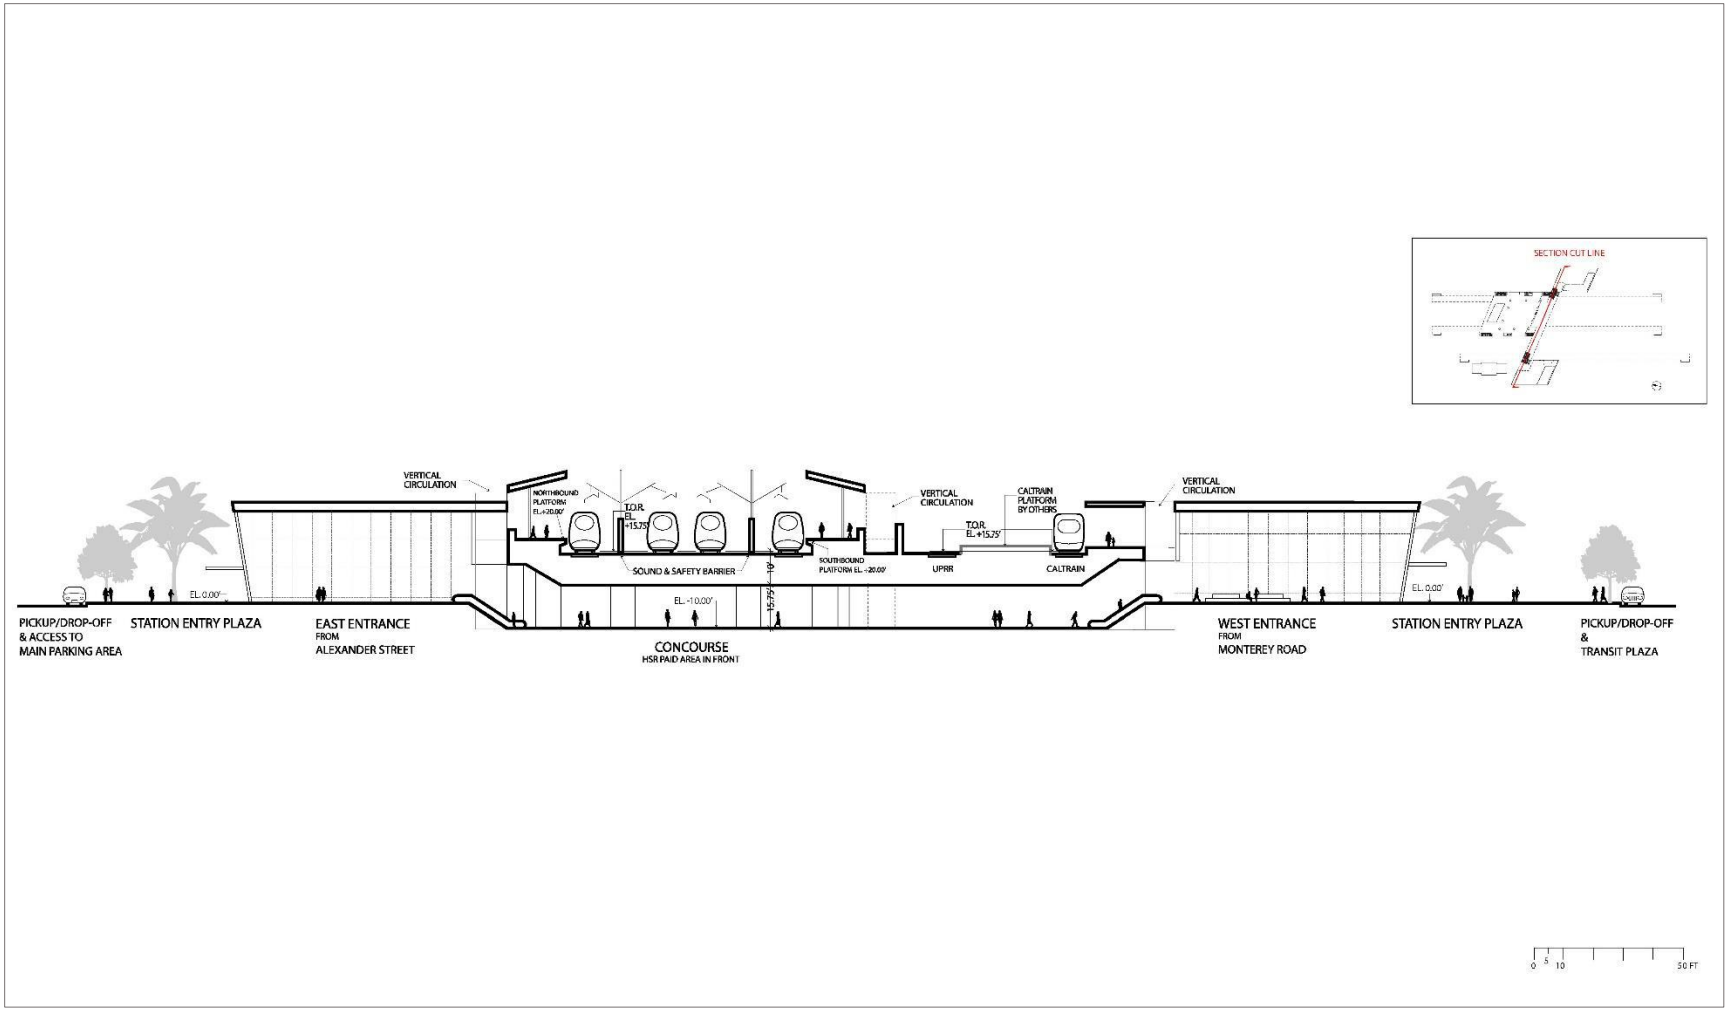
A traction power switching station would be constructed east of the HSR alignment at a location north of Paquita Espana Court or north of Palm Avenue.



Source: Authority 2019c

JUNE 2019

Figure 2-14 Conceptual Downtown Gilroy Embankment Station Plan



Source: Authority 2019c

JUNE 2019

Figure 2-15 Cross Section of Downtown Gilroy Station (Embankment)

Four traction power paralleling stations would be constructed at the following locations:

- Either the east side of the alignment between East Dunne and San Pedro Avenues or south of San Pedro Avenue
- East of the alignment, either north or south of a new Masten Avenue/Fitzgerald Avenue in-trench alignment

South of US 101, Alternative 2 would have the same two switching stations as Alternative 1:

- Either south of the alignment and west of Lovers Lane or north of the alignment and west of Lovers Lane
- In the vicinity of the Tunnel 1 east portal, either at the portal or east of SR 152 in the southern area of Casa de Fruta

PG&E would reinforce the electric power distribution network to meet HSR traction and distribution power requirements by replacing (reconductoring) the approximately 9.8-mile Metcalf to Morgan Hill and 10.6-mile Morgan Hill to Llagas 115-kV power lines. These PG&E transmission network upgrades described under Alternative 1 would also be necessary under Alternative 2.

Train Control and Communication Facilities

A total of 20 ATC sites would be constructed in the Morgan Hill and Gilroy Subsection for this alternative:

- One site east of Monterey Road north of Paquita Espana Court or at Palm Avenue, co-located with the TPSS (two site options)
- One site north of East Middle Avenue (two site options)
- One site between Las Animas Avenue and Leavesley Road
- One site south of Leavesley Road
- One site south of Lewis Street
- One site north of 6th Street in Gilroy
- Two sites south of 6th Street in Gilroy
- Two sites between 9th and 10th Streets in Gilroy
- One site south of Banes Lane

South of US 101, Alternative 2 would have the same ATC sites as Alternative 1:

- Five sites north of Carnadero Avenue
- Three sites east of the Pajaro River
- One site near Lake Road (two site options)

A total of six stand-alone communication radio sites would be constructed in this subsection at the following locations:

- Between Forsum Road and Blanchard Road (two site options)
- Near Bailey Avenue (two site options)
- Near Kirby Avenue (two site options)
- West of the intersection of Cochrane Road and Monterey Road (two site options)
- Near South Street (two site options)

South of US 101, Alternative 2 would have the same radio sites as Alternative 1:

- East of the Pajaro River south of Gilroy.

Maintenance Facilities

The MOWF under Alternative 2 would be constructed along the HSR alignment near Carnadero Avenue as described for Alternative 1 and illustrated on Figure 2-12. The freight connection would be provided as described above.

2.2.2.4 Pacheco Pass Subsection

Alignment and Ancillary Features

The characteristics of the Pacheco Pass Subsection under Alternative 2 would be the same as those described for Alternative 1 in Section 2.2.1.4, Pacheco Pass Subsection.

Wildlife Crossings

The wildlife crossings under Alternative 2 would be the same as described for Alternative 1.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

One new TPSS, Site 5—O'Neill, would be constructed approximately 1.2 miles west of the California Aqueduct as described for Alternative 1.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 2 would be the same as for Alternative 1.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.2.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

The characteristics of the San Joaquin Valley Subsection of Alternative 2 would be the same as those described for Alternative 1 in Section 2.2.1.5, San Joaquin Valley Subsection.

Wildlife Crossings

The wildlife crossings under Alternative 2 would be as described for Alternative 1.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities under Alternative 2 would be as described for Alternative 1.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 2 would be as described for Alternative 1.

Maintenance Facilities

An MOWS would be constructed near Turner Island Road near Carlucci Road as described for Alternative 1 and illustrated on Figure 2-15.

2.2.3 Alternative 3

Alternative 3 was designed to minimize the project footprint through the use of viaduct and by going around downtown Morgan Hill, as is proposed in Alternative 1. Alternative 3 would bypass downtown Gilroy to an East Gilroy Station, further minimizing interface with the UPRR corridor in

comparison to Alternative 1. The HSR guideway under this alternative would comprise 43.2 miles on viaduct, 1.8 miles at grade, 24.9 miles on embankment, 2.4 miles in trench, and two tunnels totaling 15.0 miles.

2.2.3.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

Under Alternative 3, the alignment and characteristics of this subsection would be the same as described for Alternative 2 in Section 2.2.2.1, San Jose Diridon Station Approach Subsection.

Wildlife Crossings

As under Alternative 2, there would be no wildlife crossings in this subsection.

Stations

The San Jose Diridon Station would be as described for Alternatives 1 and 2.

Traction Power Facilities

Traction power facilities under Alternative 3 would be as described for Alternative 2.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 3 would be as described for Alternative 2. No stand-alone communication radio antenna would be constructed in this subsection of Alternative 3.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.3.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The alignment and characteristics of Alternative 3 in this subsection would the same as those described for Alternative 1 in Section 2.2.1.2, Monterey Corridor Subsection.

Wildlife Crossings

As under Alternative 1, there would be no wildlife crossings in this subsection.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 3 would be as described for Alternative 1.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 3 would be as described for Alternative 1 and Alternative 2.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.3.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection under Alternative 3 would be approximately 30 miles long and located south of the Monterey Corridor Subsection. From Bernal Way in South San Jose, the alignment through Morgan Hill and San Martin would be the same as described for Alternative 1 in Section 2.2.1.3, Morgan Hill and Gilroy Subsection. The Alternative 3 alignment would diverge

from Alternative 1 by turning east north of Gilroy to arrive at the East Gilroy Station and an MOWF near SR 152. South of the MOWF, the alignment would curve generally east across the Pajaro River floodplain and through a portion of northern San Benito County before entering a tunnel (Tunnel 1) at the base of the Diablo Range. The Morgan Hill and Gilroy Subsection would end in the Pacheco Pass at Casa de Fruta Parkway/SR 152 (Figure 2-8), where the Alternative 3 alignment would converge with that of Alternatives 1 and 2.

South of the Monterey Corridor Subsection, Alternative 3 would diverge east from Alternative 1 north of Gilroy, near the intersection of Monterey Road and Church Avenue. Beginning at Church Avenue, a new freight track would diverge from the UPRR mainline to provide a freight connection to the MOWF. The freight track would continue parallel to the HSR alignment on the west side to the MOWF. The HSR alignment would cross over Church Avenue, Lena Avenue, Masten Avenue, and US 101 at Rucker Avenue on viaduct approximately 60 feet above grade. The aerial alignment would also cross over Denio Avenue and Buena Vista Avenue on viaduct before descending onto embankment. Cohansey Avenue would be closed. At the north end of the East Gilroy Station site, the alignment would cross beneath Las Animas Avenue; at the south end of the station site, Leavesley Road would be raised on a bridge over the HSR embankment. At the south end of the East Gilroy Station site, the Llagas Creek overbank flow would be directed across the HSR alignment through two culvert crossings. Farther southeast, the alignment would cross over Gilman Avenue on viaduct. The alignment would cross Llagas Creek on a low viaduct, and Holsclaw Road would be closed to vehicular traffic. Levee Road would be realigned south of Llagas Creek.

Continuing south, the alignment would ascend to approximately 25 feet above grade on embankment approaching the MOWF site. SR 152 would be grade separated and realigned, crossing over the MOWF on a bridge. Both Frazier Lake Road and Holsclaw Road would connect to the grade-separated SR 152. The MOWF, on the south side of the alignment, would have the same features as the MOWF under Alternatives 1 and 2 and would similarly be on an embankment. Additional flood detention basins would be installed around the eastern edge of the MOWF to provide sufficient flood capacity in the Soap Lake floodplain. Jones Creek would be realigned around the eastern boundary of the MOWF, crossing beneath the HSR viaduct over Bloomfield Avenue. Continuing on a 40-foot-high embankment and then on viaduct, the alignment would cross the Pajaro River, Millers Canal, Lake Road, Pacheco Creek, Lovers Lane, San Felipe Road, and SR 152 before entering the west portal of Tunnel 1. Tequisquita Slough would be partially filled by the HSR embankment, which would include cross-culverts, 3.1 acres of adjacent floodwater detention basins, and extended viaduct over Pacheco Creek to maintain floodplain capacity and function.

The Alternative 3 alignment would converge at Tunnel 1 with those of the other alternatives.

Wildlife Crossings

Wildlife crossings would be provided between Bernal Way and San Martin as described for Alternative 1 with crossings at Tulare Hill, Fisher Creek, and Llagas Creek. Although Alternative 3 would include more embankment than Alternative 1, it would be similar to Alternative 1 by continuing primarily on viaduct through the Soap Lake area to allow for wildlife movement.

Stations

Alternative 3 would enter the East Gilroy Station on embankment (approximately 17 feet to top of rail) north of Leavesley Road (Figures 2-16 and 2-17). The station platforms would be 800 feet long and the station buildings would be constructed on both the east and west sides of the tracks with a connections concourse under the tracks. The MOWF freight access track would continue through the station on the west side of the west station platform. Access for passengers arriving by auto would be available from either the east or west entrance, while the main entrance on the west side would also provide access for passengers arriving by transit or bicycle. The HSR station buildings would encompass 58,611 square feet with a 4,400-square-foot substation and systems building. The concourse would be below the tracks and embankment. Approximately 1,520 on-site parking spaces would be provided to meet the projected demand in 2040. Spaces would be located on the east and west sides of the building. The west side station parking would

be accessed from Leavesley Road and a new station access road east of the outlet mall. The east side station parking would be accessed from Marcella Avenue. A multimodal access plan would be developed prior to design and construction of the station.

Seven bus bays would be provided on site on the west side of the station. A 4,000-square-foot bicycle parking facility would be constructed; a new Class III bike route would be provided from the outlet mall to the site entrance; then Class II lanes from the station entrance to the parking. Class I bidirectional off-street path would be provided adjacent to parking which connects to the bike station. This would be a new station without any other rail operators in the station area.

Traction Power Facilities

Under Alternative 3, one new TPSS, Site 4—Gilroy, would be constructed at one of two sites: north of HSR either east or west of the former SR 152. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnection of the TPSS to a new utility switching station and/or to existing PG&E facilities, typically within tie-line/utility corridors.

As under Alternative 1, a traction power switching station would be constructed at one of two locations north of Palm Avenue and east of the alignment.

Four traction power paralleling stations would be constructed at the following locations:

- South of the alignment, located either south of Diana Avenue or at the intersection of San Pedro Avenue and Walnut Grove Drive (like Alternative 1)
- Either at the northwest or southeast corner of the HSR crossing of Masten Avenue
- South of Gilroy at one of three site options: on Lake Road north of the alignment, on Lake Road south of the alignment, or at Lovers Lane south of the alignment
- Near the Tunnel 1 east portal, either at the portal or east of SR 152 in the southern area of Casa de Fruta

The PG&E transmission network upgrades from Metcalf to Morgan Hill and from Morgan Hill to Llagas described for Alternative 1 would also be necessary under Alternative 3. In addition to a new utility switching station co-located with the TPSS, a tie-line route and power distribution to the Tunnel 1 portal under this alternative would be the same, albeit with shorter electrical line routes, as those described for Alternative 1. A distribution power line for the Tunnel 1 portals would be constructed on the south side of the alignment northeast of the intersection of Walnut Lane and SR 152, crossing over and connecting with the TPSS from the north. One power drop site would be provided at the east and west portals (two options for each portal location).

Train Control and Communication Facilities

A total of 19 ATC sites would be constructed in the Morgan Hill and Gilroy Subsection for this alternative:

- One site east of Monterey Road near Palm Avenue (two site options)
- One site near East Middle Avenue (two site options)
- Two sites near Cohansey Way
- Four sites between Las Animas Avenue and Leavesley Road
- Three sites south of Leavesley Road
- Four sites north of SR 152, east of Gilroy
- Two sites within the MOWF
- Three sites north of Bloomfield Avenue
- One site near Lake Road (two site options)

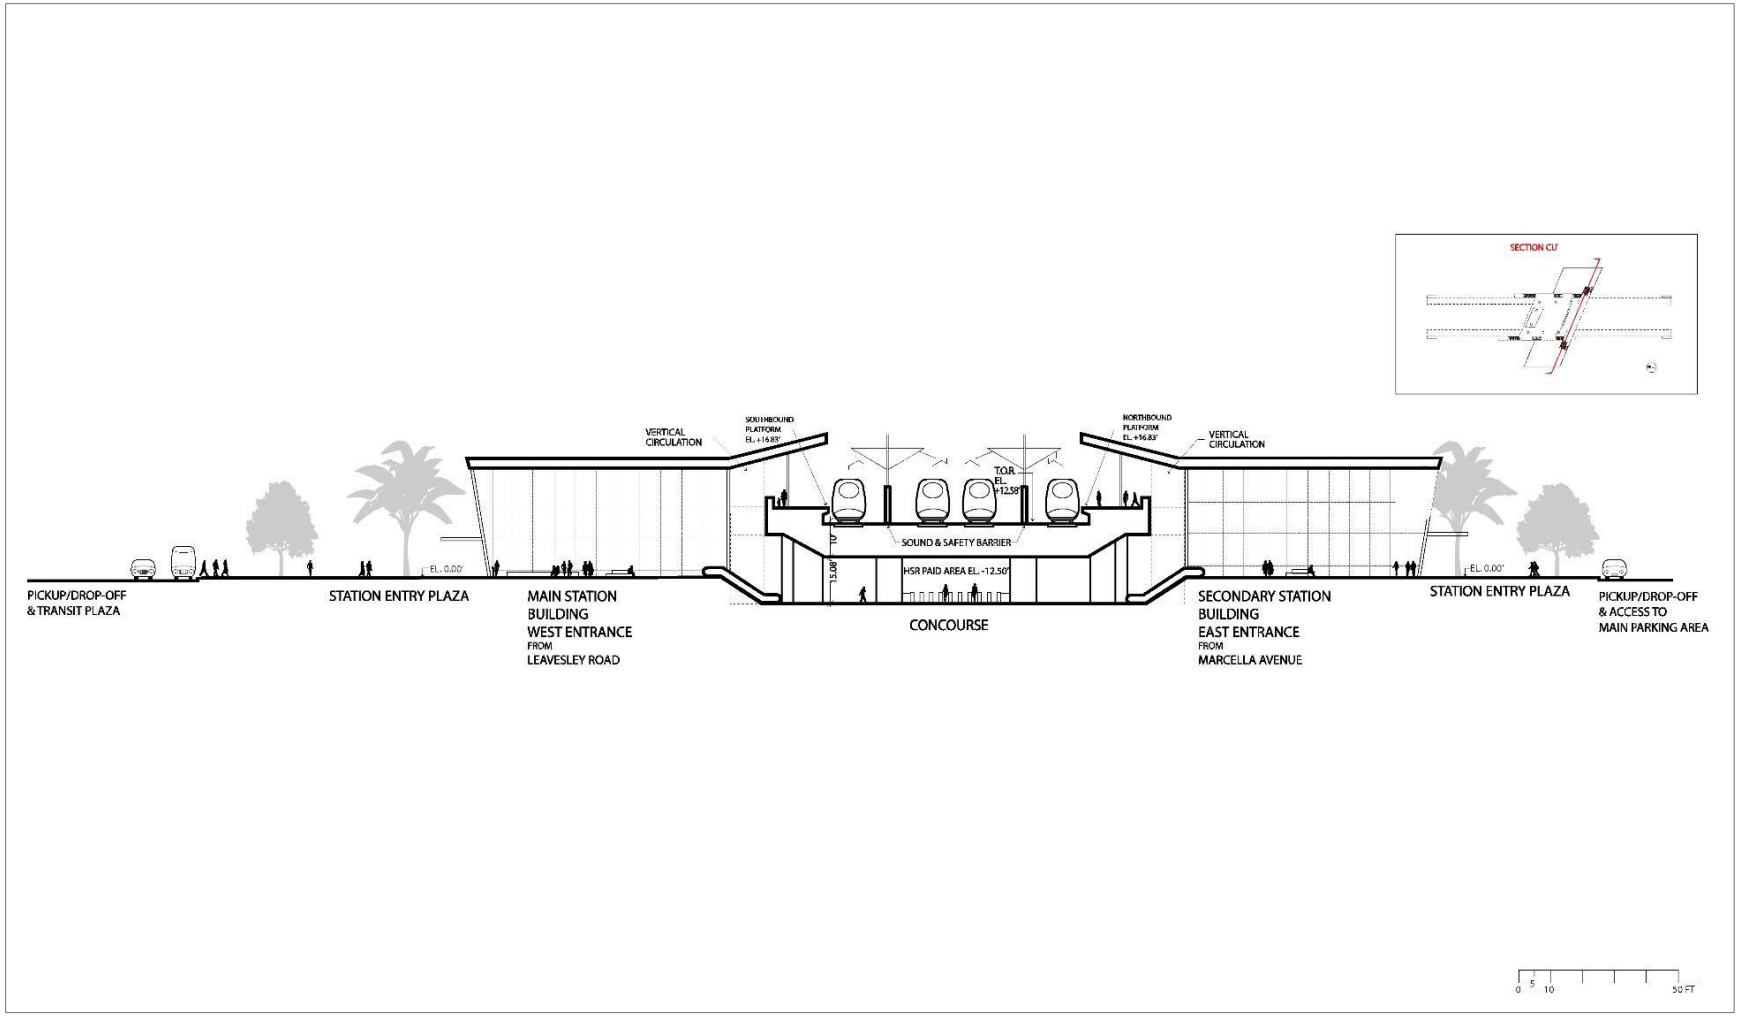
JUNE 2019

Figure 2-16 Conceptual East Gilroy Station Plan



Source: Authority 2019c

JUNE 2019

Figure 2-17 Cross Section of East Gilroy Station

A total of six stand-alone communication radio sites would be constructed in this subsection (five locations are the same as those for Alternative 1):

- Between Barnhart Avenue and Kirby Avenue (two site options)
- South of Cochrane Road along US 101 (two site options)
- North of Cox Avenue and south of West San Martin Avenue (two site options)
- At Bloomfield Avenue

Maintenance Facilities

The East Gilroy MOWF would be located west of the HSR mainline, south of the community of Old Gilroy. The MOWF would encompass approximately 75 acres and extend along the west side of the HSR alignment from the intersection of the SR 152 and Frazer Lake Road south to Jones Creek (Figure 2-18). The freight connection would be provided as described in the discussion of the alignment and ancillary facilities.

2.2.3.4 Pacheco Pass Subsection

Alignment and Ancillary Features

The characteristics of the Pacheco Pass Subsection of Alternative 3 would be the same as Alternatives 1 and 2.

Wildlife Crossings

The wildlife crossings under Alternative 3 would be as described under Alternative 1.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 3 would be as described for Alternatives 1 and 2.

Train Control and Communication Facilities

Train control and communications facilities of Alternative 3 would be as described for Alternatives 1 and 2.

Maintenance Facilities

No maintenance facilities are proposed for this subsection.

2.2.3.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

The characteristics of the San Joaquin Valley Subsection under Alternative 3 would be the same as under Alternatives 1 and 2.

Wildlife Crossings

The wildlife crossings under Alternative 3 would be as described for Alternatives 1 and 2.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities of Alternative 3 would be as described for Alternatives 1 and 2.

Train Control and Communication Facilities

Train control and communications facilities would be as described for Alternatives 1 and 2.

.

JUNE 2019

Figure 2-18 East Gilroy Maintenance of Way Facility

Maintenance Facilities

An MOWS would be constructed near Turner Island Road near Carlucci Road as described for Alternatives 1 and 2 (Figure 2-13).

2.2.4 Alternative 4 (State's Preferred Alternative, CEQA Proposed Project)

On September 17, 2019, the Authority Board of Directors reviewed a staff recommendation on the State's Preferred Alternative and a summary of key identified outreach concerns. The Board confirmed that Alternative 4 is the State's Preferred Alternative for purposes of the Draft EIR/EIS and serves as the CEQA proposed project for purposes of State CEQA Guidelines Section 15124.

The process for considering and the rationale for selecting the State's Preferred Alternative are presented in Chapter 8, Preferred Alternative, of the Final EIR/EIS.

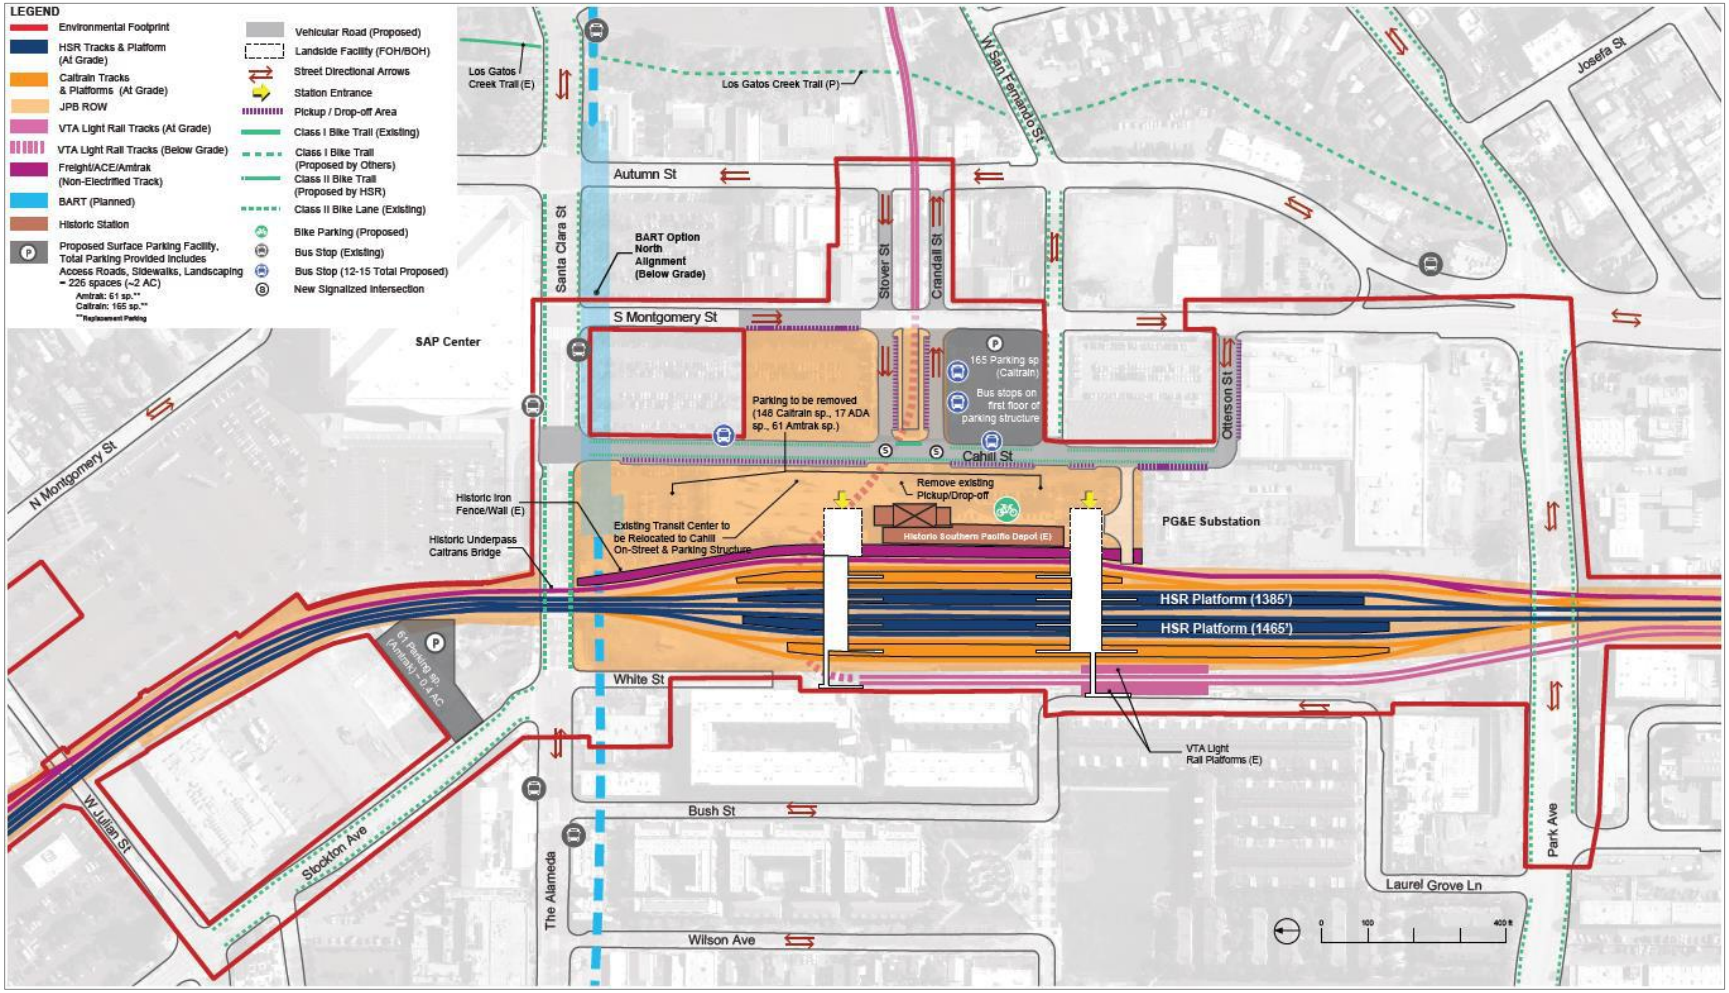
Development of Alternative 4 was intended to extend blended electric-powered passenger railroad infrastructure from the southern limit of the Caltrain Peninsula Corridor Electrification Project through Gilroy. South and east of Gilroy, HSR would operate in a dedicated guideway similar to Alternatives 1, 2, and 3. The objectives of this approach are to minimize property displacements and natural resource impacts, retain local community development patterns, improve the operational efficiency and safety of the existing railroad corridor, and accelerate delivery of electrified passenger rail services in the increasingly congested southern Santa Clara Valley corridor. The alternative is distinguished from the three other project alternatives by a blended, at-grade alignment that would operate on two electrified passenger tracks and one conventional freight track predominantly within the existing Caltrain and UPRR rights-of-way. The maximum train speed of 110 mph in the blended guideway would be enabled by continuous access-restriction fencing; four-quadrant gates, roadway lane channels, and railroad trespass deterrents at all public road grade crossings; and fully integrated communications and controls for train operations, grade crossings, and roadway traffic. Caltrain stations would be reconstructed to enable directional running as part of blended operations. Overall, this alternative would be comprised of 15.2 miles on viaduct, 30.3 miles at grade, 25.9 miles on embankment, 2.3 miles in trench, and two tunnels with a combined length of 15.0 miles.

2.2.4.1 San Jose Diridon Station Approach Subsection

Alignment and Ancillary Features

Alternative 4 would begin at Scott Boulevard in blended service with Caltrain on an at-grade profile following Caltrain MT2 and MT3 south along the east side of the existing Caltrain corridor. The existing Lafayette Street pedestrian overpass would remain in place, as would the De La Cruz Boulevard and West Hedding Street roadway overpasses. New UPRR track would start just south of Emory Street to maintain freight movement capacity north of San Jose Diridon Station. The new UPRR track would be east of Caltrain MT1. The existing College Park Caltrain Station would be reconstructed just north of Emory Street on the west side of the Caltrain Corridor on the existing siding track to eliminate the existing holdout rule at the station. A portion of both legs of the UPRR Warm Springs Subdivision Lenzen Wye would undergo minor track adjustments, and a new bridge would be built over Taylor Street for UPRR to tie into the Lenzen Wye.

The blended at-grade alignment would continue along MT2 and MT3 to enter new dedicated HSR platforms at grade at the center of San Jose Diridon Station (Figure 2-19). HSR platforms would be extended south to provide 1,385-foot and 1,465-foot platforms and would be raised to provide level boarding with the HSR trains. The existing Santa Clara Street underpass would remain, but the track in the throat and yard would require modification. There would be no need for modifications to the VTA light rail.



Source: Authority 2019c

JUNE 2019

Figure 2-19 Conceptual San Jose Diridon At-Grade Station Plan

Continuing south, the blended at-grade three-track alignment would remain in the Caltrain right-of-way through the Gardner neighborhood. The existing underpass at Park Avenue and the existing overpass at San Carlos Street would remain in place. Four-quadrant gates with channelization would be built at Auzerais Avenue and West Virginia Street. A new bridge for the blended HSR/MT3 track over I-280 would be constructed. The existing underpasses at Bird Avenue and Delmas Avenue would be reconstructed, as would the rail bridge overpasses. New standalone rail bridges over Prevost Street, SR 87, the Guadalupe River, and Willow Street would be built for MT3. MT1 and MT2 would remain on the existing structures. The existing Tamien Caltrain Station would remain in place.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

The San Jose Diridon Station would entail a four-track at-grade alignment through the center of the existing Diridon station, with 1,385- and 1,465-foot platforms centered between Santa Clara Street and Park Avenue (Figure 2-19). The existing historic train station would remain in place. A pedestrian concourse would be built above the yard to provide access to the platforms below. The concourse would consist of a pedestrian walkway above the existing Caltrain tracks and below the HSR platforms, with two entrances on the east side and one on the west.

Construction of San Jose Diridon Station would require displacement of 226 parking spaces. These would be replaced 1:1 in a parking structure at Cahill/Crandall Streets and a second site at Stockton/Alameda Streets. The existing on-site/off-street bus transit center would be relocated to an off-street facility between Cahill, Crandall, South Montgomery, and West San Fernando Streets. Street improvements would include reconfiguring and extending Cahill Street from Santa Clara Street to Otterson Street and extending Stover and Crandall Streets to South Montgomery Street. New bike lanes would be installed on the east side of Cahill Street. New signals and pedestrian crossings would be developed at Cahill and Stover Streets and Cahill and Crandall Streets.

Phasing for interim operations (2027) includes a pedestrian overhead crossing (PED OC) south of the existing historic station and would provide circulation access from the PED OC only to HSR platforms. Caltrain would continue to use the existing tunnel for access. Phasing for Valley-to-Valley (2029) includes access to and from all Caltrain and HSR platforms. At this stage, the existing tunnel would be used only for exiting purposes on HSR platforms. At buildout, there would be an additional PED OC north of the historic station with access to all Caltrain and HSR platforms. From the HSR platforms, the existing tunnel would continue to be used only for exiting.

Train Control and Communication Facilities

Under Alternative 4, HSR would use the existing ATC sites included as part of the Caltrain Positive Control and Electrification Project.

One stand-alone communications radio site would be constructed at one of two locations, both south of Scott Boulevard along the east side of the Caltrain corridor.

Maintenance Facilities

No maintenance facilities are proposed within this subsection.

2.2.4.2 Monterey Corridor Subsection

Alignment and Ancillary Features

The Monterey Corridor Subsection would be approximately 9 miles long and entirely within the San Jose city limits. From the San Jose Diridon Station Approach at West Alma Avenue, just south of the Caltrain Tamien Station, the alignment would extend primarily southeast to Bernal Way (Figure 2-4). Unlike Alternatives 1, 2, and 3, Alternative 4 would be in blended service with Caltrain on an at-grade profile within the Caltrain and UPRR right-of-way. HSR and Caltrain

would operate on the electrified MT2 and MT3 tracks, while UPRR would operate on a nonelectrified MT1. The two existing tracks would be shifted to accommodate the third track. The existing Tamien Caltrain Station would remain in place with two new electrified turnback tracks constructed south of the station to facilitate turning trains outside the station platform areas. The Michael Yard would be reconfigured to a double-ended facility to accommodate storage of Altamont Corridor Express trains and relocated to the east side of the corridor. A new standalone bridge over West Alma Avenue would be constructed for MT3 and a maintenance track, with MT1 and 2 remaining on the existing structure. A new bridge over Almaden Road would be constructed for MT2 and MT3, while MT1 would remain on the existing structures. The existing pedestrian overpass at Communications Hill would remain in place. Capitol Caltrain Station would be reconstructed with a new center platform between MT2 and MT3. The platform would be reached by a new pedestrian overpass built at the north end of the platform. The existing Capitol Expressway overpass would remain in place. Four-quadrant barrier gates with channelization would be built at Skyway Drive, Branhan Lane, and Chynoweth Avenue. The existing Blossom Hill Road overpass and adjacent pedestrian overpass would remain in place. The Blossom Hill Caltrain Station would be reconstructed; the existing pedestrian overpass and platform would be removed and a new center platform constructed between MT2 and MT3. The platform would be reached by a new pedestrian overpass built at the south end of the platform. Great Oaks Parkway would be realigned for approximately 1,350 feet to accommodate the widened rail corridor. SR 85 and Bernal Road overpasses would remain in place.

Wildlife Crossings

There would be no wildlife crossings in this subsection.

Stations

There would be no HSR stations within this subsection.

Traction Power Facilities

One traction power paralleling station would be built on the west side of the Caltrain Corridor near the Blossom Hill Caltrain Station.

Train Control and Communication Facilities

Five ATC sites would be built in the subsection:

- Near Communications Hill on the east side of the Caltrain corridor near Chateau La Salle Drive
- Near Communications Hill on the east side of the Caltrain corridor near Montecito Vista Way
- Near Communications Hill on the east side of the Caltrain corridor near Chateau La Salle Drive or Montecito Vista Way (two site options)
- Near Monterey Road on the west side of the Caltrain corridor near Capitol Caltrain Station
- Near Skyway Drive on the west side of the Caltrain corridor (two site options)
- Near Branham Lane on the west side of the Caltrain corridor

Two stand-alone communications radio sites built:

- Near Almaden Road on the east side of the Caltrain corridor
- Near Branham Lane on the west side of the Caltrain corridor

PTC sites would be constructed at the following locations:

- Two sites south of Almaden Road
- One site north of Capitol Caltrain Station
- One site co-located with the ATC site at Branham Lane

2.2.4.3 Morgan Hill and Gilroy Subsection

Alignment and Ancillary Features

The Morgan Hill and Gilroy Subsection under Alternative 4 would be approximately 32 miles long, continuing south from the Monterey Corridor Subsection. From Bernal Way in South San Jose, the alignment would extend through Morgan Hill and San Martin to the Downtown Gilroy Station, then curve generally east across the Pajaro River floodplain and through a portion of northern San Benito County before entering Tunnel 1 at the base of the Diablo Range. The alignment would exit the tunnel at Casa de Fruta Parkway/SR 152 in unincorporated eastern Santa Clara County, where it would transition to the Pacheco Pass Subsection. This subsection under Alternative 4 would be blended service with Caltrain on an at-grade profile within the Caltrain and UPRR right-of-way with an at-grade Downtown Gilroy Station. Past the Downtown Gilroy Station and south of the US 101 overpass, HSR would enter the fully grade-separated, dedicated track needed to operate HSR trains at speeds faster than 125 mph.

Beginning at the southern limit of the Monterey Corridor Subsection, the alignment would continue in blended service with Caltrain on an at-grade profile in the existing UPRR right-of-way. HSR and Caltrain would operate on the electrified MT2 and MT3 tracks, while UPRR would operate on MT1. A UPRR siding track would be provided between Blanchard Road and Bailey Avenue. Four-quadrant barrier gates would be installed at all existing public road crossings. Intrusion deterrents would be installed at all at-grade crossings. Three private roads crossing would be eliminated and alternate access provided to those properties. The existing Bailey Avenue overpass would remain in place. Under Alternative 4 the Monterey Road underpass would be reconstructed to accommodate the future widening of Monterey Road to four lanes. The Morgan Hill Caltrain Station would be reconstructed with two new side platforms built outside MT2 and MT3. The platform would be reached by a new pedestrian underpass constructed at the north end of the platform. The existing Butterfield Boulevard overpass would remain in place. Upper Llagas Creek bridge would be reconstructed.

The San Martin Caltrain Station would be reconstructed—the existing platform would be removed and a new center platform would be built between MT2 and MT3. The platform would be reached by a new pedestrian overpass constructed at the south end of the platform. The existing bridge at Miller Slough would be replaced with a triple-cell box. Blended service would end just south of the Downtown Gilroy Station, where Caltrain would have access to turn back and stabling tracks relocated from the station area to south of 10th Street on the west side of the UPRR right-of-way. The Gilroy Caltrain Station would be reconstructed—the existing Caltrain platform would be shifted south and served by a southbound station track. A northbound Caltrain side platform would be provided to the east of a northbound station track. Two side platforms would be provided for HSR on the outside of the MT2 and MT3 tracks. The platforms would be reached by a new pedestrian overpass constructed over the center of the platforms. HSR would continue south under the US 101 overpass, which would remain in place. Past the Industry spur, HSR would ascend onto embankment and then a bridge over the UPRR. Two bridges would be constructed, one for MT2 and MT3 and a separate one for the MOWF lead track. The UPRR Hollister branch line would be realigned to the west to accommodate HSR bridging over the UPRR tracks at a single location. HSR MT2 and MT3 would descend from the embankment before crossing over Bloomfield Avenue on a new structure. Four-quadrant barrier gates and intrusion deterrents would be installed at Bloomfield Avenue for the MOWF lead track and UPRR service track. HSR would continue past the MOWF and transition to a new viaduct structure to cross over Pajaro Creek. Continuing on viaduct until just west of Millers Canal, Alternative 4 would join Alternative 1 as described for Alternative 1.

Wildlife Crossings

Twelve wildlife crossings or jump-outs would be built in this subsection:

- Three adjacent wildlife crossings with jump-outs integrated into the wing walls at Tulare Hill
- Fisher Creek culvert under UPRR and Monterey Road replaced with a larger box culvert to improve wildlife crossing potential at this location
- Wildlife crossings and integrated jump-outs south of Emado Avenue, south of Fisher Road, and south of Live Oak
- Wildlife crossings at Richmond Avenue, Paquita Espana Court, and north of Kalana Avenue
- Dedicated jump-outs north of Fisher Creek, south of Blanchard Road, north of Kalana Avenue, and at Miramonte Avenue

Wildlife intrusion deterrents would be constructed for at-grade crossings at Blanchard Road, Palm Avenue, Live Oak Avenue, and Bloomfield Avenue.

Stations

The Downtown Gilroy Station approach would be at grade with dedicated HSR tracks to the west of UPRR between Old Gilroy Street/7th Street, which would be closed, and 9th Street (Figure 2-20). A new HSR station with 800-foot platforms would be built south of the existing Caltrain station. A pedestrian concourse would be built above the UPRR and Caltrain tracks to provide access to the platforms below.

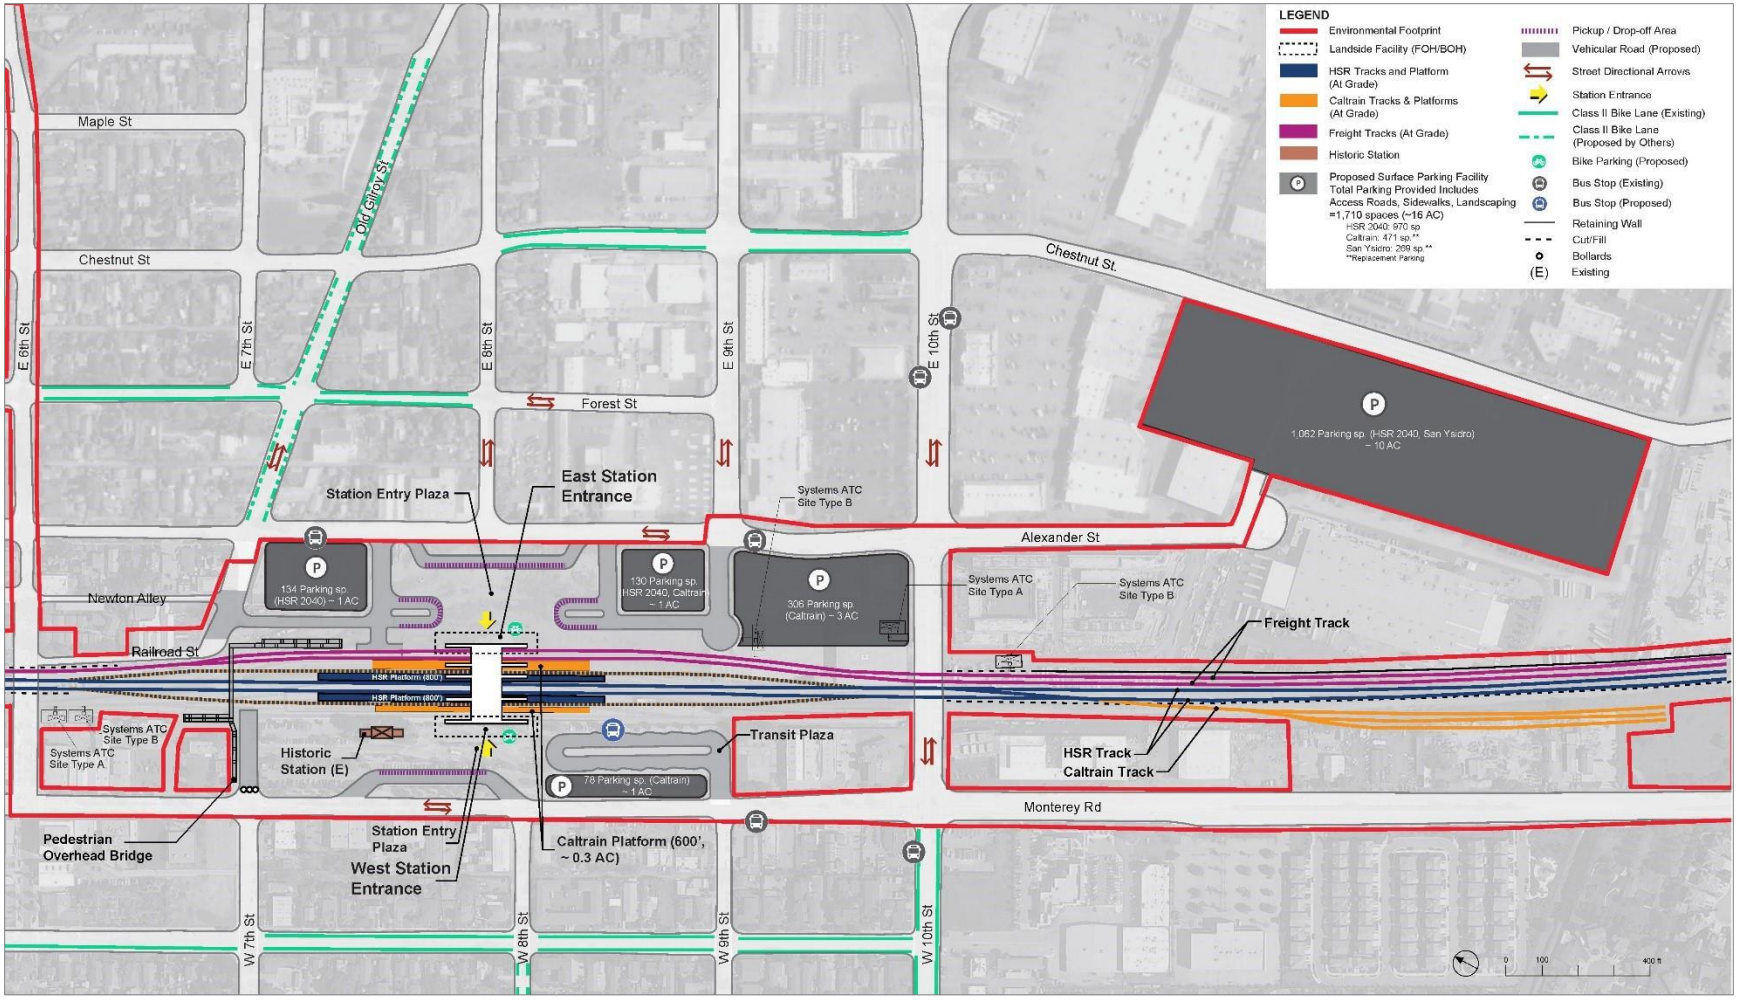
The existing 489 Caltrain parking spaces on the west side of the station would be replaced 1:1 in parking lots on the east and west sides of the alignment. The existing 269 parking spaces at the San Ysidro housing development would be replaced 1:1 with new surface parking at the south end of Alexander Street. HSR parking demand would be 970 spaces in 2040, for a total of 1,728 aggregated parking spaces in 2040. The station site plan provides 970 new parking spaces in five areas. One site would be west of the station along Monterey Road at 9th Street. The other four would be on the east side of the station along Alexander Avenue at 7th Street, 9th Street, 10th Street, and Banes Lane. A multimodal access plan would be developed prior to design and construction of the station. The plan would be developed in coordination with local agencies and would include a parking strategy that would specify the location, amount, and phasing of parking.

A total of eight bus bays would be provided, adding one bay to the existing seven. East 7th Street would be closed and East 10th Street would be modified with quadrant gates and channelization. A pedestrian overcrossing would be installed to provide access between East and West 7th Street. A 4,000-square-foot bicycle facility would be constructed. Figure 2-20 illustrates the conceptual at-grade Downtown Gilroy Station.

The Morgan Hill Caltrain Station would be reconstructed with two new side platforms built outside MT2 and MT3. The platform would be reached by a new pedestrian underpass built at the north end of the platform. The San Martin Caltrain Station would be reconstructed where the existing platform would be removed and a new center platform would be built between MT2 and MT3. The platform would be reached by a new pedestrian overpass constructed at the south end of the platform.

Traction Power Facilities

One new TPSS, Site 4—Gilroy, would be constructed at one of two locations on the east side of the alignment: south of Buena Vista Avenue or north of Cohansey Avenue. At this site, one new utility switching station could be co-located with the TPSS. Communication facilities (i.e., redundant [two underground or one underground and one overhead on existing power structures] fiber optic lines) would also be required to support the electrical interconnections of the TPSS to a new PG&E switching station and/or to existing PG&E facilities, typically within tie-line/utility corridors.



Source: Authority 2019c

JUNE 2019

Figure 2-20 Conceptual Downtown Gilroy At-Grade Station Plan

A traction power switching station would be constructed west of the HSR alignment at Richmond Avenue.

Three traction power paralleling stations would be constructed adjacent to the guideway:

- Either south of San Pedro Avenue on the west side of the alignment or just north of Butterfield Boulevard on the east side of the alignment
- West of Lovers Lane either south of the alignment or north of the alignment (like Alternative 1)
- Near the Tunnel 1 east portal, either at the portal or east of SR 152 in the southern area of Casa de Fruta (like Alternatives 1 and 2)

PG&E would reinforce the electric power distribution network to meet HSR traction and distribution power requirements by replacing (reconductoring) approximately 11.1 miles of existing power line associated with the Spring to Llagas and Green Valley to Llagas 115-kV power lines. The existing power lines to be reconductored, reusing the poles and towers, begin at the Morgan Hill Substation on West Main Avenue in Morgan Hill, then cross the east side of Peak Avenue and Dewitt Avenue, spanning West Dunne Avenue, Chargin Drive, Spring Avenue, and several residences. The alignment would continue south across an open-space area, then follow Sunnyside Avenue for approximately 0.5 mile. The alignment would continue south for approximately 4 miles, spanning additional open-space areas of wineries and the Corde Valley Golf Course. The alignment would then turn east along the north side of Day Road before heading south for approximately 2.5 miles and terminating at the Llagas Substation in Gilroy.

A permanent overhead distribution electrical power line from TPSS Site 4 to the Tunnel 1 portal location would provide power to the tunnel boring machine during construction and the tunnel fire-life-safety system during operations.

Train Control and Communication Facilities

Twenty-two ATC sites would be constructed:

- One site south of Blanchard Road on the east side of the alignment (two site options)
- Three sites south of Live Oak Avenue on the west side of the alignment
- One site north of San Pedro Avenue on the west side of the alignment
- One site north of Barrett Avenue on the west side of the alignment (two site options)
- One site north of East Middle Avenue on the west side of the alignment
- One site in the vicinity of either Church Avenue or Lena Avenue on the east side of the alignment (two site options)
- One site between Leavesley Road and IOOF Avenue
- Two sites south north of Lewis Street on the east side of the alignment
- Two sites south of 6th Street on the west side of the alignment
- Three sites in the vicinity of 10th Street on the east side of the alignment
- Four sites north of Carnadero Avenue on the west side of the alignment
- Two sites east of the Pajaro River
- One site near Lake Road (two site options) (like Alternative 1)

PTC sites would be constructed at the following locations:

- One site south of Blanchard Road
- One site north of Bailey Avenue
- One site co-located with ATC site south of Live Oak Avenue

- One site at Cohansey Avenue
- One site south of Lewis Street
- One site south of East 6th Street

Five stand-alone communications radio sites would be constructed:

- Near Bernal Way on the west side of the alignment (two site options)
- South of Live Oak Avenue on the west side of the alignment (two site options)
- In the vicinity of East Central Avenue (two site options, one on either side of the alignment)
- South of California Avenue on the east side of the alignment
- East of the Pajaro River south of Gilroy

Maintenance Facilities

The South Gilroy MOWF (Figure 2-21) near Bloomfield Avenue would encompass approximately 50 acres and the program and layout would be as described for Alternatives 1 and 2. In contrast to Alternatives 1 and 2, the MOWF for Alternative 4 would be located on the west side of the tracks between Carnadero Avenue and the Pajaro River. This configuration would require realignment of the UPRR Hollister Subdivision. HSR mainline and MOWF lead track would pass over UPRR Coast Subdivision tracks.

2.2.4.4 Pacheco Pass Subsection

Alignment and Ancillary Features

Alternative 4 would be as described for Alternatives 1–3 for this subsection.

Wildlife Crossings

The wildlife crossings under Alternative 4 would be as described for Alternatives 1–3.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

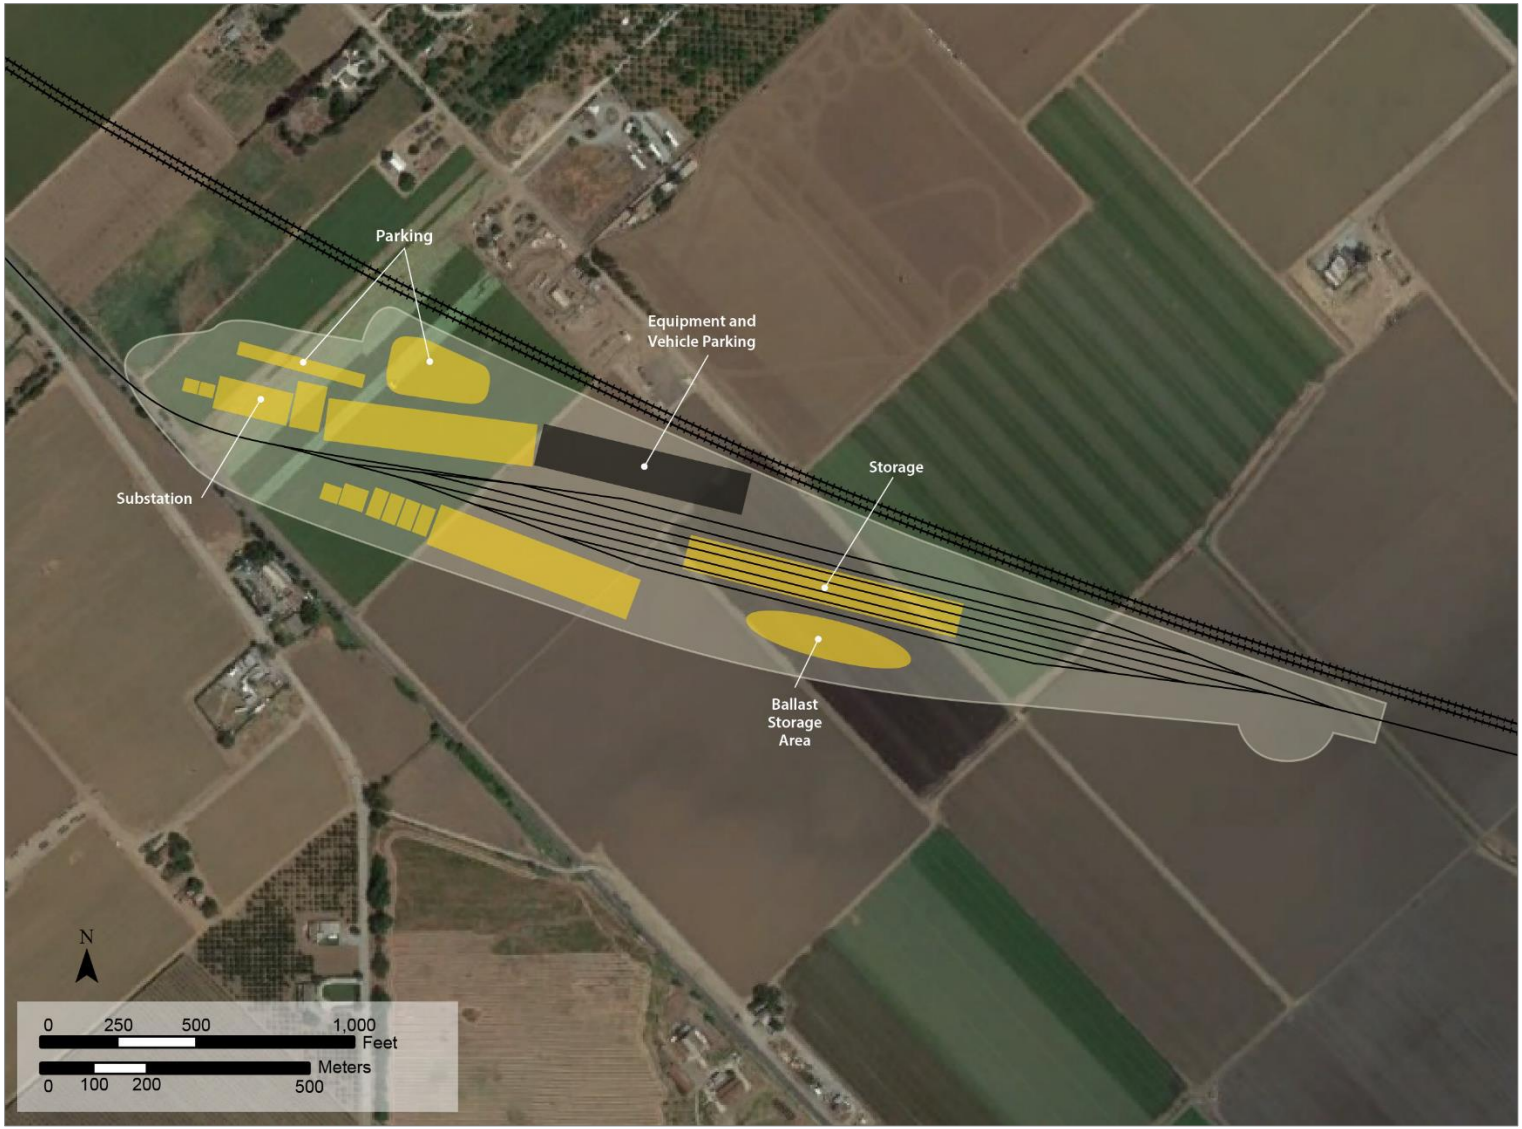
Traction power facilities of Alternative 4 would be as described for Alternatives 1–3.

Train Control and Communication Facilities

Train control and communications facilities would be as described for Alternatives 1–3.

Maintenance Facilities

An MOWS would be built near Turner Island Road near Carlucci Road as described for Alternatives 1–3 (Figure 2-13).



Source: Authority 2019c

JUNE 2019

Figure 2-21 South Gilroy Maintenance of Way Facility for Alternative 4

2.2.4.5 San Joaquin Valley Subsection

Alignment and Ancillary Features

Alternative 4 would be the same as described for Alternatives 1–3 for this subsection.

Wildlife Crossings

The wildlife crossings under Alternative 4 would be as described for Alternatives 1–3.

Stations

No new HSR stations are proposed for this subsection.

Traction Power Facilities

Traction power facilities would be as described for Alternatives 1–3.

Train Control and Communication Facilities

Train control and communications facilities would be as described for Alternatives 1–3.

Maintenance Facilities

An MOWS would be built near Turner Island Road near Carlucci Road as described for Alternatives 1–3 (Figure 2-13).

2.3 Impact Avoidance and Minimization Features

The Authority has developed impact avoidance and minimization features (IAMF) that would avoid or minimize potential noise and vibration effects. IAMFs are incorporated into the project design and construction to avoid or minimize environmental effects. The description of each IAMF details the means and effectiveness of the feature in avoiding or minimizing effects, as well as the environmental benefits of implementing the measure. Table 2-2 shows complete descriptions of all IAMFs that the Authority and FRA would implement to address potential effects related to noise and vibration.

Table 2-2 Noise and Vibration Impact Avoidance and Minimization Features

IAMF	Description
NV-IAMF#1: Noise and Vibration	Prior to construction, the contractor will prepare and submit to the Authority a noise and vibration technical memorandum documenting how the FTA and FRA guidelines for minimizing construction noise and vibration impacts will be employed when work is being conducted within 1,000 feet of sensitive receptors. Typical construction practices contained in the FTA and FRA guidelines for minimizing construction noise and vibration impacts include the following: ▪ Construct noise barriers, such as temporary walls or piles on excavated material, between noisy activities and noise-sensitive resources. ▪ Route truck traffic away from residential streets where possible. ▪ Construct walled enclosures around especially noisy activities or around clusters of noisy equipment. ▪ Combine noisy operations so that they occur in the same period. ▪ Phase demolition, earthmoving, and ground-impacting operations so as not to occur in the same time period. ▪ Avoid impact pile driving where possible in vibration-sensitive areas.

FTA = Federal Transportation Administration
FRA = Federal Railroad Administration

3 LAWS, REGULATIONS, AND ORDERS

This chapter provides a summary of federal, state, and local laws, regulations, orders, or plans that pertain to noise and vibration in the geographic area that would be affected by the project.

3.1 Federal

3.1.1 Noise Control Act of 1972 (42 U.S.C. § 4910)

The Noise Control Act of 1972 (42 United States Code [U.S.C.] § 4910) was the first comprehensive statement of national noise policy. It declared, "it is the policy of the U.S. to promote an environment for all Americans free from noise that jeopardizes their health or welfare." Although the act, as a funded program, was ultimately abandoned at the federal level, it served as the catalyst for comprehensive noise studies and the generation of noise assessment and mitigation policies, regulations, ordinances, standards, and guidance for many states, counties and municipal governments. For example, the noise elements of community general plans and local noise ordinances studied as part of this technical report were largely created in response to passage of the act.

3.1.2 Occupational Safety and Health Administration Occupational Noise Exposure (29 C.F.R. § 1910.95)

The Occupational Safety and Health Administration has regulated worker noise exposure to a time-weighted-average of 90 A-weighted decibels (dBA) over an 8-hour work shift. Areas where levels exceed 85 dBA must be designated and labeled as high-noise-level areas where hearing protection is required. This noise exposure criterion for workers would apply to construction activities in the RSA. Noise from construction activities might also elevate noise levels at nearby construction sites to levels that exceed 85 dBA and thus trigger the need for administrative or engineering controls and hearing conservation programs for worker safety, as detailed by the Occupational Safety and Health Administration.

3.1.3 Federal Railroad Administration

3.1.3.1 Noise and Vibration Impact Assessment Guidelines

The FRA provides guidance regarding the evaluation of noise and vibration impacts of HSR trains in the FRA guidance manual (FRA 2012). The manual includes prediction methodology, assessment procedures, and impact criteria for noise and vibration. The noise and vibration impact criteria are discussed in this technical report in Section 4.1.3, Impact Criteria, and Section 4.2.3, Impact Criteria, respectively.

3.1.3.2 Railroad Noise Emission Compliance Regulations (49 C.F.R. Part 210)

The FRA's Railroad Noise Emission Compliance Regulation (49 Code of Federal Regulations [C.F.R.] Part 210) prescribes minimum compliance regulations for enforcement of Noise Emission Standards for Transportation Equipment; Interstate Rail Carriers (40 C.F.R. Part 201) adopted by the U.S. Environmental Protection Agency. New locomotives must meet the following noise standards: 70 dBA at 100 feet while stationary at idle throttle setting, 87 dBA at 100 feet while stationary at all other throttle settings, 90 dBA at 100 feet while moving. Rail cars must meet the following noise standards: 88 dBA at 100 feet while moving at speeds of 45 mph or less, and 93 dBA at 100 feet while moving at speeds greater than 45 mph.

Whether or not the EPA standard applies to high-speed trainsets, the analysis in this EIR/EIS does not assume that Authority trainsets will comply with it because the Authority and FRA are not aware of any high-speed trainsets manufactured in the world today that meet this standard at all speeds. A noise-generation standard specific to high-speed trains does exist in Europe (European TSI Standard), and a trainset manufactured to that standard complies with the US EPA standard (if applicable) generally at speeds below 190 to 200 mph. Above that speed, airflow over the trainset and its pantograph and related apparatus is the main source of noise, which presently-known technology cannot resolve to comply with the US EPA standard (if applicable). The analysis in this EIR/EIS – both prior to mitigation and after mitigation – assumes

a trainset generating noise in compliance with the European TSI standard, because trainsets currently in manufacture and operation in Europe can meet this standard; the analysis does not assume a trainset that meets the US EPA standard.

3.1.3.3 Locomotive Horn Rule (49 C.F.R. Part 222 & Part 229)

FRA regulations require that engineers sound their locomotive horns while approaching public grade crossings until the lead locomotive fully occupies the crossing. In general, the regulations require locomotive engineers to begin to sound the train horn for a minimum of 15 seconds, and a maximum of 20 seconds, in advance of public grade crossings. Engineers must also sound the train horn in a standardized pattern of two long, one short and one long blast and the horn must continue to sound until the lead locomotive or train car occupies the grade crossing. Additionally, the minimum sound level for the locomotive horn is 96 dB(A), while the maximum sound level is 110 dB(A), both measured at 100 feet forward of the locomotive.

FRA allows public authorities to establish a quiet zone, which is segment of a rail line, within which is situated one or a number of consecutive public road-rail crossings at which locomotive horns are not routinely sounded, provided sufficient safety measures are implemented at the crossing to prevent/minimize the potential for accidents to occur. Railroad authorities, including Caltrain, CHSRA and railroad companies (such as UPRR) cannot establish quiet zones; only local cities and counties can establish them by applying to the FRA.

At a minimum, new quiet zones must be at least one-half mile in length and contain at least one public grade crossing (i.e., a location where a public highway, road, or street crosses one or more railroad tracks at grade). Every public grade crossing in a quiet zone must be equipped at a minimum with active grade crossing warning devices consisting of flashing lights and gates.

If a public authority wants to establish a new quiet zone, it must conduct an assessment of hazards related to the crossings in the proposed zone and implement sufficient safety measures to reduce the proposed quiet zone's risk level to an acceptable level. Improvements may include: Roadway medians or channelization devices to discourage motorists from driving around a lowered crossing gate; a four-quadrant gate system to block all lanes of highway traffic; converting a two-way street into a one-way street and installing crossing gates, and permanent or temporary (nighttime) closure of the crossing to highway traffic. As an alternative, communities may also choose to silence routine locomotive horn sounding through the installation of wayside horns at public grade crossings. Wayside horns are train-activated stationary acoustic devices at grade crossings that are directed at highway traffic as a one-for-one substitute for train horns.

As described in Chapter 2, Alternatives, the project includes the following improvements in all blended service segments with at-grade crossings: fencing of the right of way; four-quadrant gates and roadway channelization at at-grade crossings, and intrusion detection and monitoring systems The installation of these features would assist local cities and counties to establish quiet zones should they decide to do so but cities or counties would need to go through the quiet zone process with the FRA first to establish such zones.

3.1.4 Federal Transit Administration Guidelines

The FTA provides guidance regarding the evaluation of noise and vibration impacts associated with construction and operations of non-high-speed trains in the FTA guidance manual (FTA 2018). The manual includes prediction methods, assessment procedures, and impact criteria for noise and vibration. Although it was originally developed for use on public mass transit projects the FTA guidance manual includes a method that is applicable to HSR station activities, yard and maintenance facility activities, and conventional-speed rail operations. The FTA construction noise and vibration assessment method is consistent with the FRA method. The noise and vibration impact criteria are discussed in this technical report in Section 4.1.3 and Section 4.2.3, respectively.

3.1.5 Federal Highway Administration Procedures for Abatement of Highway Traffic Noise and Construction Noise (23 C.F.R. Part 772)

The FHWA stipulates procedures and criteria for noise assessment studies of highway projects (23 C.F.R. Part 772). It requires that noise abatement measures be considered on all major highway projects if the project would cause a substantial increase in traffic noise levels or if projected traffic noise levels approach or exceed the noise abatement criteria level for activities occurring on adjacent lands. These noise criteria are assigned to exterior and interior activities.

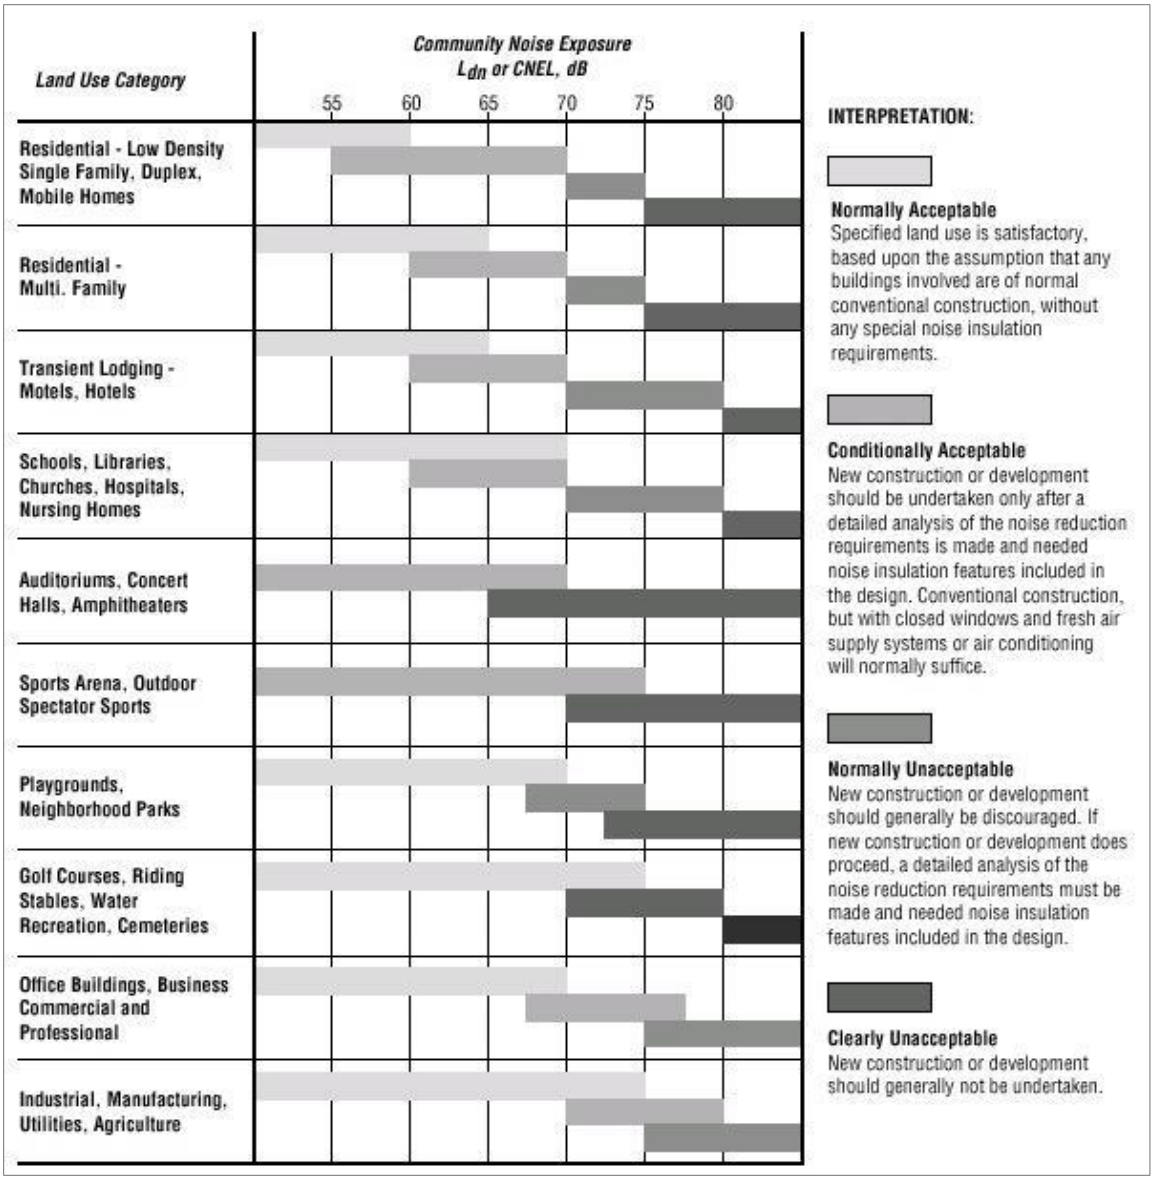
If motor vehicle traffic noise from federally funded projects is predicted to approach or exceed the noise abatement criteria during the noisiest 1-hour period, noise abatement measures must be considered, and, if determined to be reasonable and feasible, they must be incorporated as part of the project. Consistent with FHWA guidelines, the California Department of Transportation (Caltrans) defines *approach* as being within 1 dBA of the noise abatement criteria. Caltrans criteria also consider that a 12-decibel (dB) increase in peak-noise-hour traffic noise is a significant increase as defined by the FHWA procedures.

3.2 State

3.2.1 General Plan Guidelines (Cal. Gov. Code § 65302(f)), Appendix C, Noise Element Guidelines

The noise element of a community's general plan provides a basis for a comprehensive local program to control and abate environmental noise and to protect citizens from excessive exposure. The California Governor's Office of Planning and Research *General Plan Guidelines* (OPR 2003) outlines the development of the noise element for local agencies.

Figure 3-1 from the noise compatible land use planning guidance is often adopted by city and county agencies for land use planning purposes for acoustical compatibility based on existing ambient noise levels in the community. For example, commercial land uses are considered appropriate where existing noise levels might be considered too high for residential development.



Source: OPR 2003

Figure 3-1 State of California Land Use Compatibility Guidelines

3.2.2 California Department of Transportation Traffic Noise Analysis Protocol

The Caltrans *Traffic Noise Analysis Protocol* (Caltrans 2011) establishes guidelines for evaluating traffic noise impacts along highways where frequent outdoor use takes place and for determining reasonable and feasible noise abatement measures. These criteria are relevant to the extent that the project would result in reconstruction or reconfiguration of an existing highway or traffic lanes, or would affect traffic patterns. Under FHWA (23 C.F.R. Part 772) and Caltrans policies, noise barriers should be considered for transportation improvement projects when various traffic noise abatement criteria are exceeded.

3.2.3 California Noise Control Act of 1973 (Cal. Health and Safety Code, Division 28, Noise Control Act, § 46000 et seq.)

The relevant legacy of the California Noise Control Act of 1973 was the development of the required content of the Noise Element of General Plans. This legislation provides guidance to local governments for preparing the required noise elements in city and county general plans, pursuant to California Government Code Section 65302(f).

3.3 Regional and Local

Counties and cities in California prepare general plans with noise policies and ordinances (outlined in the discussion of state regulations). In preparing the noise element, a city or county must identify local noise sources, and analyze and quantify, to the extent practicable, current and projected noise levels for various sources. These sources may include highways and freeways; passenger and freight railroad operations; ground rapid transit systems; commercial, general, and military aviation and airport operations; and other ground stationary noise sources (these would include HSR alignments). Noise-level contours must be mapped for these sources using the community noise equivalent level (CNEL) or the day-night sound level (L_{dn}), and are to be used as a guide in land use decisions to minimize the exposure of community residents to excessive noise.

These noise elements often incorporate specific allowable noise levels to achieve a quality environment. Where airports exist- many airports identify an airport noise impact area, which identifies adverse noise impacts within the 65 CNEL noise contour generated by the airport. In some instances, general plans include the existing L_{dn} near airports. The HSR system is not subject to local general plan policies and ordinances related to noise limits or to locally based criteria concerning noise and vibration for the project alternatives.

Table 3-1 shows a summary of noise and vibration elements in the plans and policies adopted by the cities and counties in the RSA that were identified and considered in the preparation of this analysis.

Table 3-1 Applicable Local Plans and Policies

Plan/Policy Document	Summary
Santa Clara County	
Santa Clara County General Plan (1994)	The *Santa Clara County General Plan* was adopted in 1994 with amendments published in 2016. The general plan includes the following strategies, policies, and implementation recommendations relevant to noise and vibration: **Strategy 1: Prevent or Minimize Noise Conflicts** ▪ Policy C-HS 24: Environments for all residents of Santa Clara County free from noises that jeopardize their health and well-being should be provided through measures which promote noise and land use compatibility. ▪ Policy C-HS 25: Noise impacts from public and private projects should be mitigated. – Implementation C-HS(i) 24: Where necessary, construct sound walls or other noise mitigations. – Implementation C-HS(i) 25: Prohibit construction in areas which exceed applicable interior and exterior standards, unless suitable mitigation measures can be implemented.
Santa Clara County Ordinance Code (2016)	The Santa Clara Ordinance Code was originally adopted in 1972. The Code establishes the following sections of Division B11, Chapter VIII, Control of Noise and Vibration, relevant to noise and vibration: **Section B11-152. – Exterior noise limits** Maximum permissible sound levels by receiving land use:

Plan/Policy Document	Summary
	▪ The noise standards for the various receiving land use categories as presented in [the following bullets, derived from Table B11-152] will apply to all property within any zoning district: – One and Two-Family Residential – 45 dBA between 10 pm to 7 am, and 55 dBA between 7 am to 10 pm; – Multiple Family Dwelling – 50 dBA between 10 pm and 7 am; – Residential Public Space – 55 dBA between 7 am to 10 pm; – Commercial – 60 dBA between 10 pm and 7 am, and 65 dBA between 7 am to 10 pm; – Light Industrial – 70 dBA at all times; and – Heavy Industrial – 75 dBA at all times. ▪ No person may operate or cause to be operated any source of sound at any location within the unincorporated territory of the County or allow the creation of any noise on property owned, leased, occupied or otherwise controlled by the person, which causes the noise level when measured on any other property either incorporated or unincorporated, to exceed: a) The noise standard for that land use as specified [above] for a cumulative period of more than 30 minutes in any hour; or b) The noise standard plus five dB for a cumulative period of more than 15 minutes in any hour; or c) The noise standard plus ten dB for a cumulative period of more than five minutes in any hour; or d) The noise standard plus 15 dB for a cumulative period of more than one minute in any hour; or e) The noise standard plus 20 dB or the maximum measured ambient, for any period of time. **Sec. B11-153. – Interior noise standards** Maximum permissible dwelling interior sound levels: ▪ The interior noise standards for multifamily residential dwellings as presented in [the following bullet, derived from Table B11-153] will apply, unless otherwise specifically indicated, within all dwellings: – Multi-Family Dwelling – 35 dBA allowable interior noise level between 10 pm and 7 pm, and 45 dBA between 7 am and 10 pm. ▪ No person will operate or cause to be operated within a dwelling unit any source of sound or allow creation of any noise which causes the noise level when measured inside a neighboring receiving dwelling unit to exceed: a) The noise standard as specified [above] for a cumulative period of more than five minutes in any hour; or b) The noise standard plus five dB for a cumulative period of more than one minute in any hour; or c) The noise standard plus ten dB or the maximum measured ambient, for any period of time. – If the measured ambient level exceeds that permissible within any of the noise limit categories above, the allowable noise exposure standard will be increased in five-dB increments in each category as appropriate to reflect the ambient noise level. **Section B11-154. – Prohibited acts**

Plan/Policy Document	Summary
	• Construction/demolition a) Operating or causing the operation of any tools or equipment used in construction, drilling, repair, alteration or demolition work between weekdays and Saturday hours of 7 p.m. and 7 a.m., or at any time on Sundays or holidays, that the sound therefrom creates a noise disturbance across a residential or commercial real property line, except for emergency work of public service utilities or by variance. b) Where technically and economically feasible, construction activities will be conducted in a manner that the maximum noise levels at affected properties will not exceed those listed in the following schedule: i. Mobile equipment. Maximum noise levels for nonscheduled, intermittent, short-term operation (less than ten days) of mobile equipment: [See full ordinance for table of maximum noise levels] ii. Stationary equipment. Maximum noise levels for repetitively scheduled and relatively long-term operation (periods of ten days or more) of stationary equipment are as follows: [See full ordinance for table of maximum noise levels] ▪ Vibration a) Operating or permitting the operation of any device that creates a vibrating or quivering effect that: i. Endangers or injures the safety or health of human beings or animals; or ii. Annoys or disturbs a person of normal sensitivities; or iii. Endangers or injures personal or real properties.
City of Santa Clara	
City of Santa Clara 2010-2035 General Plan (2010)	The City of Santa Clara adopted the 2010-2035 General Plan on November 16, 2010. Updates were published in 2013 and 2014. The general plan includes the following environmental quality goals and policies which are applicable to noise and vibration: Goals ▪ 5.10.6-G1 Noise sources restricted to minimize impacts in the community. ▪ 5.10.6-G2 Sensitive uses protected from noise intrusion. Policies ▪ 5.10.6-P2 Incorporate noise attenuation measures for all projects that have noise exposure levels greater than General Plan “normally acceptable” levels. ▪ 5.10.6-P6 Discourage noise sensitive uses, such as residences, hospitals, schools, libraries and rest homes, from areas with high noise levels, and discourage high noise generating uses from areas adjacent to sensitive uses. ▪ 5.10.6-P10 Encourage transit agencies to develop and apply noise reduction technologies for their vehicles to reduce the noise and vibration impacts of Caltrain, Bay Area Rapid Transit, future High Speed Rail, light rail and bus traffic.

Plan/Policy Document	Summary
Santa Clara City Code (2017)	The Santa Clara City Code is current through Ordinance 1969, passed in 2017. Chapter 9.10, Regulation of Noise and Vibration, is relevant to noise and vibration: **9.10.040 Noise or sound regulation:** [. . .] The maximum noise or sound levels are set forth, as follows: ▪ Category 1: Single Family and Duplex Residential – 55 dBA between 7 am to 10 pm, and 50 dBA between 10 pm to 7 am; ▪ Category 2: Multiple Family Residential – 55 dBA between 7 am to 10 pm; 50 dBA between 10 pm and 7 am; ▪ Category 3: Commercial, Office – 65 dBA between 7 am and 10 pm, and 60 dBA between 10 pm and 7 am; ▪ Light Industrial – 70 dBA at all times; and ▪ Heavy Industrial – 75 dBA at all times. **9.10.050 Vibration regulation:** [. . .] Vibration [should not exceed] the vibration perception threshold of an individual at the closest property line point to the vibration source on the real property affected by the vibration.
City of San Jose	
Envision San Jose 2040 General Plan (2011)	The *Envision*: *San Jose 2040 General Plan* was adopted in 2011. The Plan establishes the following goals and policies relevant to noise and vibration: **Goal EC-1 – Community Noise Levels and Land Use Compatibility.** Minimize the impact of noise on people through noise reduction and suppression techniques, and through appropriate land use policies. ▪ **Policy EC-1.1:** Locate new development in areas where noise levels are appropriate for the proposed uses. Consider federal, state and City noise standards and guidelines as a part of new development review. **Interior Noise Levels** – The City's standard for interior noise levels in residences, hotels, motels, residential care facilities, and hospitals is 45 dBA DNL. […] **Exterior Noise Levels** – The City's acceptable exterior noise level objective is 60 dBA DNL or less for residential and most institutional land uses. The acceptable exterior noise level objective is established for the City, except in the environs of the San José International Airport and the Downtown, as described below: – For new multi-family residential projects, the residential component of mixed-use development, [and single family residential uses] use a standard of 60 dBA DNL in usable outdoor activity areas [. . .] ▪ **Policy EC-1.2:** Minimize the noise impacts of new development on land uses sensitive to increased noise levels (Categories 1, 2, 3 and 6) by limiting noise generation and by requiring use of noise attenuation measures such as acoustical enclosures and sound barriers, where feasible. The City considers significant noise impacts to occur if a project would: – Cause the DNL at noise sensitive receptors to increase by five dBA DNL or more where the noise levels would remain "Normally Acceptable"; or – Cause the DNL at noise sensitive receptors to increase by three dBA DNL or more where noise levels would equal or exceed the "Normally Acceptable" level. ▪ **EC-1.7** Require construction operations within San José to use best available noise suppression devices and techniques and limit construction hours near residential uses per the City's Municipal Code. The City considers significant construction noise

Plan/Policy Document	Summary
	impacts to occur if a project located within 500 feet of residential uses or 200 feet of commercial or office uses would: – Involve substantial noise generating activities (such as building demolition, grading, excavation, pile driving, use of impact equipment, or building framing) continuing for more than 12 months. For such large or complex projects, a construction noise logistics plan that specifies hours of construction, noise and vibration minimization measures, posting or notification of construction schedules, and designation of a noise disturbance coordinator who would respond to neighborhood complaints will be required to be in place prior to the start of construction and implemented during construction to reduce noise impacts on neighboring residents and other uses. ▪ **Policy EC-1.9** Require noise studies for land use proposals where known or suspected loud intermittent noise sources occur which may impact adjacent existing or planned land uses. For new residential development affected by noise from heavy rail, light rail, BART or other single-event noise sources, implement mitigation so that recurring maximum instantaneous noise levels do not exceed 50 dBA Lmax in bedrooms and 55 dBA Lmax in other rooms. **Goal EC-2 – Vibration. Minimize vibration impacts on people, residences, and business operations.** ▪ **Policy EC-2.1:** Near light and heavy rail lines or other sources of ground-borne vibration, minimize vibration impacts on people, residences, and businesses through the use of setbacks and/or structural design features that reduce vibration to levels at or below the guidelines of the Federal Transit Administration. Require new development within 100 feet of rail lines to demonstrate prior to project approval that vibration experienced by residents and vibration sensitive uses would not exceed these guidelines. ▪ **Policy EC-2.2:** Require new sources of ground-borne vibration, such as transit along fixed rail systems or the operation of impulsive equipment, to minimize vibration impacts on existing sensitive land uses to levels at or below the guidelines of the Federal Transit Administration. ▪ **Policy EC-2.3** Require new development to minimize vibration impacts to adjacent uses during demolition and construction. For sensitive historic structures, a vibration limit of 0.08 in/sec PPV (peak particle velocity) will be used to minimize the potential for cosmetic damage to a building. A vibration limit of 0.20 in/sec PPV will be used to minimize the potential for cosmetic damage at buildings of normal conventional construction.

Plan/Policy Document	Summary
San Jose Municipal Code (2017)	The San Jose Municipal Code, codified through Ordinance No. 29912, was last adopted in May 2017. The Code includes the following titles and chapters relevant to noise and vibration: **Chapter 20.100: Administration and Permits** The City of San José does not establish quantitative noise limits for demolition or construction activities occurring in the City. According to San José Municipal Code, the legal hours of construction within 500 feet of a residential unit are limited to the hours of 7:00 a.m. to 7:00 p.m. on Monday through Friday. The City's Municipal Code also contains a Zoning Ordinance that limits noise levels generated by stand-by/backup and emergency generators. The noise level emitted by these generators shall not exceed 55 decibels at the property line of residential properties. The standards and criteria for stand-by/ backup generators are set as follows: ▪ Maximum noise levels, based upon a noise analysis by an acoustical engineer, will not exceed the applicable noise standards set forth in Title 20.80.2030. ▪ Testing of generators is limited to 7 a.m. to 7 p.m., Monday through Friday.

Plan/Policy Document	Summary
City of Morgan Hill	
Morgan Hill 2035 General Plan (2016)	The Morgan Hill 2035 General Plan was adopted in 2016. The Plan includes the following goals and policies relevant to noise and vibration: **Goal SSI-8. Prevention of noise from interfering with human activities or causing health problems Policies** ▪ **Policy SSI-8.1 Exterior Noise Level Standards.** Require new development projects to be designed and constructed to meet acceptable exterior noise level standards, as follows: – Apply a maximum exterior noise level of 60 dBA Ldn in residential areas where outdoor use is a major consideration (e.g., backyards in single-family housing developments and recreation areas in multi-family housing projects). Where the City determines that providing an Ldn of 60 dBA or lower cannot be achieved after the application of reasonable and feasible mitigation, an Ldn of 65 dBA may be permitted. – Indoor noise levels should not exceed an Ldn of 45 dBA in new residential housing units. – Noise levels in new residential development exposed to an exterior Ldn 60 dBA or greater should be limited to a maximum instantaneous noise level (e.g., trucks on busy streets, train warning whistles) in bedrooms of 50 dBA. Maximum instantaneous noise levels in all other habitable rooms should not exceed 55 dBA. The maximum outdoor noise level for new residences near the railroad shall be 70 dBA Ldn, recognizing that train noise is characterized by relatively few loud events. ▪ **Policy SSI-8.3 Commercial and Industrial Noise Level Standards**. Evaluate interior noise levels in commercial and industrial structures on a case-by-case basis based on the use of the space. ▪ **Policy SSI-8.4 Office Noise Level Standards.** Interior noise levels in office buildings should be maintained at 45 dBA Leq (hourly average) or less, rather than 45 dBA Ldn (daily average). ▪ **Policy SSI-8.5 Traffic Noise Level Standards.** Consider noise level increases resulting from traffic associated with new projects significant if: a) the noise level increase is 5 dBA Ldn or greater, with a future noise level of less than 60 dBA Ldn, or b) the noise level increase is 3 dBA Ldn or greater, with a future noise level of 60 dBA Ldn or greater. ▪ **Policy SSI-8.6 Stationary Noise Level Standards.** Consider noise levels produced by stationary noise sources associated with new projects significant if they substantially exceed existing ambient noise levels. ▪ **Policy SSI-9.3 Sound Wall Design.** The maximum height of sound walls shall be eight feet [. . .]

Plan/Policy Document	Summary
Morgan Hill Municipal Code (2017)	The Morgan Hill Municipal Code was originally published in 1987. The current code is updated through Ordinance Number 2256 N.S., enacted June 28, 2017. The following sections from Chapter 8.28, Noise, of Title 8, Health and Safety, of the municipal code are applicable to noise and vibration: **8.28.040 – Enumeration of unlawful noises.** Unlawful noises include: **D.1. Construction activities as limited below**. "Construction activities" are defined as including but not limited to excavation, grading, paving, demolition, construction, alteration or repair of any building, site, street or highway, delivery or removal of construction material to a site, or movement of construction materials on a site. Construction activities are prohibited other than between the hours of seven a.m. and eight p.m., Monday through Friday and between the hours of nine a.m. to six p.m. on Saturday. Construction activities may not occur on Sundays or federal holidays. […] **I. Noises Adjacent to Schools, Courts, Churches and Hospitals**. The creation of any excessive noise on any street adjacent to any school, institution of learning, church or court while the same is in use or adjacent to any hospital, which noise unreasonably interferes with the workings of such institution or which disturbs or unduly annoys patients in the hospital; provided, conspicuous signs are displayed in such streets indicating that the street is adjacent to a school, hospital or court; **J. Pile Drivers, Hammers and Similar Equipment.** The operation, between the hours of eight p.m. and seven a.m. of any pile driver, steam shovel, pneumatic hammer, derrick, steam or electric hoist or other appliance, the use of which is attended by loud or unusual noise.
City of Gilroy	
The City of Gilroy 2002-2020 General Plan (2002)	The City of Gilroy 2002-2020 General Plan was adopted in 2002. The Plan includes the following goals and policies relevant to noise and vibration from Chapter 8, Community Resources and Potential Hazards. **GOAL:** Protection of Gilroy residents from exposure to excessive noise and its effects through appropriate mitigation measures and responsive land use planning, especially in regard to noise-sensitive land uses such as schools, hospitals, and housing for seniors. ▪ **Policy 26.02 Maximum Permissible Noise Levels.** Ensure that outdoor and indoor noise levels are within the maximum permitted levels (see Figure A- 27). ▪ **Policy 26.04 Acoustical Design.** Consider the acoustical design of projects in the development review process to reduce noise to an acceptable level. Ensure that noise mitigation features are designed and implemented in an aesthetically pleasing and consistent manner. ▪ **Policy 26.05 Earth Berms.** Require landscaped earth berms as an alternative to soundwalls where feasible to buffer noise along major thoroughfares adjacent to residential areas. Where an earth berm is not feasible, a masonry wall screened with drought tolerant, low maintenance landscaping should be required.

Plan/Policy Document	Summary
Gilroy Municipal Code (2017)	The Gilroy Municipal Code is current through Ordinance 2017-03, passed in 2017. The Code includes the following chapters relevant to noise and vibration. **Chapter 16, Offences—Miscellaneous** **Section 16.38 Hours of construction** of the Gilroy Municipal Code states the following regarding construction noise: 2 Unless otherwise provided for in a validly issued permit or approval, construction activities shall be limited to the hours of 7 a.m. and 7 p.m., Monday through Friday and 9 a.m. to 7 p.m. on Saturday. Construction activities shall not occur on Sundays or city holidays, which include: New Years Day, Memorial Day, Independence Day, Labor Day, Thanksgiving Day and Christmas. "Construction activities" are defined as including but not limited to, excavation, grading, paving, demolitions, construction, alteration or repair of any building, site, street or highway, delivery or removal of construction material to a site, or movement of construction materials on a site. […] **Chapter 30, Zoning Ordinance** **30.41.31 Specific provisions—Noise.** It shall be unlawful to generate noise within the city limits that exceeds the limits established in this section. (b) Maximum Outdoor Noise Levels. (2) Commercial and Industrial Noise Impacting Residentially Zoned Properties. Noise emanating from properties that are zoned for uses other than residential is limited to a maximum of 70 dBA (L10) measured at the residential property line. Such noise is limited to the hours of 7 a.m. to 10 p.m., and prohibited between the hours of 10 p.m. and 7 a.m.
San Benito County	
San Benito County 2035 General Plan (2015)	The San Benito County 2035 General Plan was adopted in 2015. The Plan includes the following goals and policies relevant to noise and vibration: **Health and Safety** **Goal HS-8:** To protect the health, safety, and welfare of county residents through the elimination of annoying or harmful noise levels. ▪ **Policy HS-8.1 Project Design.** The County shall require new development to comply with the noise standards shown in the tables in Figure A-29 through proper site and building design, such as building orientation, setbacks, barriers (e.g., earthen berms), and building construction practices. The County shall only consider the use of soundwalls after all design-related noise mitigation measures have been evaluated or integrated into the project or found infeasible. ▪ **Policy HS-8.2 Acoustical Analysis.** The County shall require an acoustical analysis to be performed prior to development approval where proposed land uses may produce or be exposed to noise levels exceeding the "normally acceptable" criteria (e.g. "conditionally acceptable", "normally unacceptable") shown in Table 9-2. Land uses should be prohibited from locating, or required to mitigate, in areas with a noise environment within the "unacceptable" range. ▪ **Policy HS-8.3 Construction Noise.** The County shall control the operation of construction equipment at specific sound intensities and frequencies during day time hours between 7 a.m. and 6 p.m. on weekdays and 8 a.m. and 5 p.m. on Saturdays. No construction shall be allowed on Sundays or federal holidays.

Plan/Policy Document	Summary
	▪ **Policy HS-8.7 Acceptable Vibration Levels.** The County shall require construction projects anticipated to generate a significant amount of vibration to ensure acceptable interior vibration levels at nearby noise-sensitive uses based FTA criteria. ▪ **Policy HS-8.10 Reduction in Noise Levels at Existing Land Uses**. Reduce traffic noise levels where expected to significantly impact sensitive receptors through the installation of noise control measures such as quiet pavement surfaces, noise barriers, traffic calming measures, and interior sound insulation treatments. ▪ **Policy HS-8.12 Construction Noise Control Plans.** Require all construction projects to be constructed within 500 feet of sensitive receptors to develop and implement construction noise control plans that consider the following available controls in order to reduce construction noise levels as low as practical: – Utilize 'quiet' models of air compressors and other stationary noise sources where technology exists; – Equip all internal combustion engine-driven equipment with mufflers, which are in good condition and appropriate for the equipment; – Locate all stationary noise-generating equipment, such as air compressors and portable power generators, as far away as possible from adjacent land uses; – Locate staging areas and construction material areas as far away as possible from adjacent land uses; – Prohibit all unnecessary idling of internal combustion engines; – Notify all abutting land uses of the construction schedule in writing; and – Designate a "disturbance coordinator" (e.g. contractor foreman or authorized representative) who would be responsible for responding to any local complaints about construction noise. The disturbance coordinator will determine the cause of the noise complaint (e.g., starting too early, bad muffler, etc.) and will require that reasonable measures warranted to correct the problem be implemented. Conspicuously post a telephone number for the disturbance coordinator at the construction site and include it in the notice sent to neighbors regarding the construction schedule.

Plan/Policy Document	Summary
San Benito County Ordinance Code (2016)	The San Benito County Ordinance Code, codified through Ordinance 937, was most recently adopted in 2015. The Code includes Chapter 19.39, Noise Control Regulations, of Title 19, Land Use and Environmental Regulations, relevant to noise and vibration: **Article IV. Sound Level Restrictions** **19.39.030 MAXIMUM PERMISSIBLE SOUND PRESSURE LEVELS.** No person shall operate, or permit to be operated, on private property any source of sound in such a manner as to create: (A) A sound pressure level which exceeds the limits set forth for the receiving land use category in Table 1 [summarized in the following bullets] which may be measured at or within the real property boundary of the receiving land use, or its vertical extension: ▪ Rangeland, Productive Rural Lands, and Rural Transitional – 45 dBA day and 35 dBA night ▪ Single Family Residential, Residential Multiple, and Planned Unit Development – 50 dBA day, 40 dBA night ▪ Commercial – 65 dBA day and 55 dBA night ▪ Controlled Manufacturing, Light Industrial, and Heavy Industrial – 70 dBA day and 60 dBA night (B) A sound pressure level which exceeds the limits set forth for the receiving land use category in Table A- 5 for more than 15 minutes in 60 minutes which may be measured at or within the real property boundary of the receiving land use, or its vertical extension; or I An equivalent A-weighted sound level that exceeds the limits set forth for the receiving land use category in Table A- 5 which may be measured at or within the real property boundary of the receiving land use or its vertical extension. (D) A sound level that exceeds the ambient sound level by 5 dB which may be measured at or within the real property boundary of the receiving land use or its vertical extension.

Plan/Policy Document	Summary
Frazier Lake Airpark Comprehensive Land Use Plan (2001)	The Frazier Lake Airpark Comprehensive Land Use Plan was adopted by the San Benito County Airport Land Use Commission in 2001. The following compatibility guidelines are relevant to noise and vibration: **4.3.1 Noise Compatibility:** The objective of noise compatibility criteria is to minimize the number of people exposed to frequent and/or high levels of aircraft noise. ▪ The maximum CNEL considered clearly acceptable for residential uses in the vicinity of the Airport is 55 dB CNEL. ▪ Noise level compatibility standards for other types of land uses shall be applied in the same manner as the above residential noise level criteria. Table 4-1 presents acceptable noise levels for other land uses in the vicinity of the Airport. ▪ Single-event noise levels should be considered when evaluating the compatibility of highly noise sensitive land uses such as schools, libraries, and outdoor theaters. Single-event noise levels are especially important in the areas regularly overflown by aircraft, but which do not produce significant CNEL contours.
Merced County	

2030 Merced County General Plan (2013)	The 2030 Merced County General Plan was adopted in 2013. The Plan includes the following goals and policies relevant to noise and vibration:
	Public Facilities and Services
	▪ **Policy PFS-8.7: Incompatible Land Uses near Schools.** Coordinate with school districts to reduce the effects of incompatible land uses and noise adjacent to school facilities.
	Health and Safety
	Goal HS-7: Protect residents, employees, and visitors from the harmful and annoying effects of exposure to excessive noise.
	▪ **Policy HS-7.4: New Noise or Groundborne Vibration Generating Uses.** Require new commercial and industrial uses to minimize encroachment on incompatible noise or groundborne vibration sensitive land uses. Also consider the potential for encroachment by residential and other noise or groundborne vibration sensitive land uses on adjacent lands that could significantly impact the viability of the commercial or industrial areas.
	▪ **Policy HS-7.5: Noise Generating Activities.** Limit noise generating activities, such as construction, to hours of normal business operation.
	▪ **Policy HS-7.9: Transportation Project Construction/Improvements.** Require transportation project proponents to prepare all acoustical analysis for all roadway and railway construction projects in accordance with Policy HS-7.2; additionally, rail projects shall require the preparation of a groundborne vibration analysis in accordance with Policy HS-7.2. Consider noise mitigation measures to reduce traffic and/or rail noise levels to comply with Table HS-1 standards if pre-project noise levels already exceed the noise standards of Table HS-1 and the increase is significant. The County defines a significant increase as follows:
	  ▪ Pre-Project Noise Environment of Less than 60 dB – 5+ dB would result in a significant increase
	  ▪ Pre-Project Noise Environment of between –0 - 65 dB – 3+ dB would result in a significant increase
	  ▪ Pre-Project Noise Environment greater than 65 dB – 1.5+ dB would result in a significant increase
	▪ **Policy HS-7.11: Train Whistle Noise.** Support improvements to crossings in urban areas in order to eliminate the need for train whistle blasts near or within communities.

Plan/Policy Document	Summary
Merced County Ordinance Code (2016)	The Merced County Ordinance Code is current through Ordinance 1951, passed in 2017. The Code includes Chapter 10.60, Noise Control, of Title 10, Public Health and Safety, relevant to noise and vibration: **10.60.030 Sound level limitations.** A. No person shall cause, suffer, allow, or permit the operation of any sound source on private property in such a manner as to create a sound level that results in any of the following, when measured at or within the real property line of the receiving property: 1. Exceeds the background sound level by at least 10 dBA during daytime hours (7 a.m. to 10 p.m.) and by at least 5 dBA during nighttime hours (10 p.m. to 7 a.m.). The background sound level for purposes of this section shall be determined as set forth in Section 10.60.060; or 2. Exceeds 65 dBA Ldn on residential real property or 70 dBA Ldn on nonresidential real property; or 3. Exceeds 75 dBA Lmax on residential real property or 80 dBA Lmax on nonresidential real property. B. The following are exempt from the sound level limits of Section 10.60.030(A): 5. Noise from construction activity, provided that all construction in or adjacent to urban areas shall be limited to the daytime hours between 7 a.m. and 6 p.m., and all construction equipment shall be properly muffled and maintained.

L_{eq} = sound level equivalent
FTA = Federal Transit Administration
CNEL = community noise equivalent level

4 METHODS FOR EVALUATING IMPACTS

Analysts evaluated the effects of noise and vibration from construction and operations of the project quantitatively using FRA-approved methods. Construction noise and vibration and high-speed ground transportation noise and vibration were evaluated in accordance with methods and criteria from the FRA guidance manual (FRA 2012). Non-high-speed transit noise and vibration and noise levels from passenger stations, transfer power facilities and maintenance facilities were evaluated in accordance with the FTA guidance manual (FTA 2018). Train horn noise was evaluated using the FRA horn noise model. Highway noise was evaluated in accordance with the FHWA's *Procedures for Abatement of Highway Traffic Noise and Construction Noise* (23 C.F.R. Part 772) as defined by the Caltrans *Traffic Noise Analysis Protocol* (Caltrans 2011). Analysts used design information on the project alternatives and operations assumptions from the Authority's *Connecting and Transforming California, 2016 Business Plan* (2016 Business Plan) (Authority 2016) and its *Connecting California, Expanding Economy, Transforming Travel, 2018 Business Plan n* (2018 Business Plan) (Authority 2018) in the noise and vibration models, as well as field noise and vibration measurements, and professional judgment.

This technical report evaluates both direct and indirect noise and vibration effects. Direct effects consist of increases in noise and vibration because of construction activities or operations, while indirect effects for noise include the project's effect on traffic patterns, which indirectly affect noise levels. This chapter provides additional details of the methods for the noise and vibration assessments.

4.1 Noise

4.1.1 Descriptors

Noise is typically described as an unwanted sound[6] that is disagreeable or undesirable. Several factors affect sound as perceived by the human ear, including the amplitude (or loudness), the frequency (or pitch), and the time variation (or duration).

The amplitude of a sound is determined by the magnitude of fluctuation caused by sound waves in the air pressure above and below the atmospheric pressure at equilibrium. It is usually expressed in dB, which are logarithmic values of the ratio of the pressure produced by the sound wave to a reference pressure.[7] Decibels more understandably express the extremely large range of absolute sound pressure values that the human ear is capable of perceiving. For example, a train horn sound of 100 dB has about 5,600 times greater pressure than a very low sound of 35 dB typically found in a quiet rural environment.

The frequency describes the tonal character of noise. Individual frequencies or a range of frequencies are expressed in terms of the rate of fluctuation of the air pressure in cycles per seconds or Hertz (Hz). The average human ear and brain system can generally perceive noise frequencies between 20 Hz and 20,000 Hz. However, the human hearing system does not respond equally to all frequencies; it is more sensitive to mid-band frequencies (e.g., 500 to 2,000 Hz). Thus, when describing sound and its effects on a human population, dBA sound pressure levels are used to account for the response of the human ear by de-emphasizing the low and very high frequency components of the sound. The A-weighted sound level correlates well with human response and is expressed in terms of a single number. Figure 4-1 illustrates typical A-weighted noise levels of high-speed trains (including the German TransRapid TR08 maglev system, the French TGV, and the American Amtrak Acela train), as well as other indoor and outdoor noise sources. Typical A-weighted sound levels range from the 40s to the 90s (dBA), where 40 is very quiet and 90 is very loud. On average, each A-weighted sound level increase of 10 dB corresponds to an approximate doubling of subjective loudness.

---

[6] Sound is caused by transmission of energy that propagates as waves of alternating pressure through a medium (fluids, solids, or gases such as the air).

[7] The standard reference sound pressure is 20 micro-Pascals as indicated in ANSI S1.8-1969 *Preferred Reference Quantities for Acoustical Levels.*

FEBRUARY 2019

Figure 4-1 Typical A-Weighted Maximum Sound Levels

The level of environmental noise commonly varies with time. There are several descriptors (also called *metrics*) to characterize environmental noises according to their duration. This analysis uses the following single-number descriptors, all based on the dBA sound pressure levels as the fundamental unit for environmental noise measurements, computations, and assessment:

- **Sound exposure level (SEL)**—The SEL describes noise exposure from a single noise event. It is represented by the total A-weighted sound energy during the event, normalized to a 1-second interval. The SEL decibel value is as if all the sound energy during the event would have occurred in 1 second. This is also the reason that SEL decibels may not be directly compared to normal sound level decibels. The SEL is the primary descriptor of HSR vehicle noise emissions and an intermediate value in the calculation of both equivalent sound level (L_{eq}) and L_{dn} (defined in the following text). Impact criteria for noise effects on livestock are also based on SEL.

- **L_{eq}**—The L_{eq} is the logarithmic summation of noise exposure during a period of interest, and it is widely used as a single-number descriptor of environmental noise. L_{eq} is used in this document to report results of short-term noise measurements and to calculate the L_{dn}. The FRA and FTA have adopted hourly L_{eq} ($L_{eq}(h)$) as the measure of cumulative noise impact for nonresidential land uses.
- **L_{dn}**—The L_{dn} is the A-weighted L_{eq} for a 24-hour period with a 10 dB penalty applied to noise levels occurring between 10:00 p.m. and 7:00 a.m. As a result, the L_{dn} considers the number of noise events during day and night separately, as well as the duration of each event, which is affected by vehicle speed. Studies have shown that the L_{dn} is well correlated with human annoyance for community noise. The FRA and FTA have adopted it as a measure of cumulative noise impact for residential land uses.
- **CNEL**—The CNEL is a 24-hour average A-weighted sound level for a given day, with the addition of a 5 dB penalty to sound levels occurring from 7:00 p.m. to 10:00 p.m., and with the addition of a 10 dB penalty to sound levels occurring from 10:00 p.m. to 7:00 a.m. Although the CNEL was developed and used in California for many years, L_{dn} is now the descriptor of choice.

The use of different descriptors may result in different numerical values for a given sound or acoustic environment even though the actual properties of the sound or environment such as amplitude, frequency, and duration are not altered. Because of this, some comparisons of dB may not be appropriate or may be invalid, such as comparing the SEL value to the maximum sound level (L_{max}) or to the L_{eq} of a train passby. Comparisons using the same metric however, may be very useful to evaluate different sounds or noise sources. Additional information about these noise descriptors is included in Section A.1 of the FRA guidance manual (FRA 2012).

4.1.2 Resource Study Area

The RSA is the area in which all environmental investigations specific to noise are conducted to determine the resource characteristics and potential effects of the project alternatives. The noise RSA extends approximately 2,500 feet from the alternatives' centerlines and includes all sensitive receptors potentially exposed to noise impacts. This noise RSA is larger than the maximum FRA-recommended screening distances for high-speed trains shown in Table 4-1. The maximum FRA-recommended screening distance for a new HSR corridor is 1,300 feet in quiet suburban or rural environments with train operation speeds greater than 170 mph; however, this recommendation assumes there would be 50 train operations per day. Consistent with FRA methods, analysts extended the noise RSA for the project farther than the maximum FRA-recommended screening distances to reflect the frequency of train operations, which would exceed 200 trains per day based on the Authority's 2016 Business Plan and 2018 Business Plan (Authority 2016, 2018).

Table 4-1 Federal Railroad Administration Recommended Screening Distances for Evaluation of HSR Noise Impacts[1]

Corridor Type	Existing Noise Environment	Screening Distance for Project Type and Speed Regime (feet from centerline)[2]	
		90 to 170 mph	> 170 mph
Railroad	Urban/noisy suburban—unobstructed	300	700
	Urban/noisy suburban—intervening buildings[3]	200	300
	Quiet suburban/rural	500	1,200
Highway	Urban/noisy suburban—unobstructed	250	600
	Urban/noisy suburban—intervening buildings[3]	200	350
	Quiet suburban/rural	400	1,100
New Rail	Urban/noisy suburban—unobstructed	350	700
	Urban/noisy suburban—intervening buildings[3]	250	350
	Quiet suburban/rural	600	1,300[4]

Source: FRA 2012
mph = miles per hour
[1] Noise screening distances for Regime II (mechanical noise resulting from wheel/rail interactions and guideway vibrations) and Regime III (aerodynamic noise resulting from airflow moving past the train)
[2] Measured from centerline of guideway or rail corridor. Minimum distance is assumed 50 feet.
[3] Rows of buildings assumed to be at 200 feet, 400 feet, 600 feet, 800 feet, and 1,000 feet parallel to the guideway.
[4] Distance was extended to 2,500 feet for analysis of the project.

4.1.3 Impact Criteria

4.1.3.1 Construction

The FRA guidance manual (FRA 2012) includes construction noise assessment criteria as shown in Table 4-2. An 8-hour L_{eq} and a 30-day average noise exposure L_{dn} are used to assess impacts. A 30-day average L_{dn} is used to assess impacts in residential areas, and a 30-day average 24-hour L_{eq} is used to assess impacts in commercial and industrial areas. The noise emission levels of the construction equipment, utilization factor, hours of operation, and location of equipment are used to calculate 8-hour and 30-day average noise exposures. FRA assessment criteria are used throughout the RSA.

Table 4-2 Detailed Assessment Criteria for Construction Noise

Land Use	8-Hour L_{eq} (dBA)		L_{dn} (dBA) 30-Day Average
	Day	Night	
Residential	80	70	75
Commercial	85	85	80[1]
Industrial	90	90	85[1]

Source: FRA 2012
L_{eq} = equivalent sound level
L_{dn} = day-night sound level
dBA = A-weighted decibel
[1] 24-hour L_{eq}, not L_{dn}

4.1.3.2 Operations

For the HSR system, analysts used noise impact criteria adopted by the FRA to assess the contribution of the noise from project operations and construction to the existing environment. Analysts used criteria adopted by the FTA to assess the contribution of the noise from

conventional speed rail operations and stationary facilities. These guidelines establish methods for analyzing and assessing noise and vibration impacts. The FRA noise impact criteria are based on maintaining a noise environment considered acceptable for land uses where noise may have an effect. Land use also factors into the determination of impact; while impacts on industrial uses are not considered, places where people sleep or where quiet is an integral component of the land use require evaluation to determine if noise impact would occur. Descriptions of the three land use categories are shown in Table 4-3. The noise exposure is measured in terms of L_{dn} for residential land uses or in terms of $L_{eq}(h)$ for other land uses.

Table 4-3 Federal Railroad Administration Land Use Categories for Noise Exposure

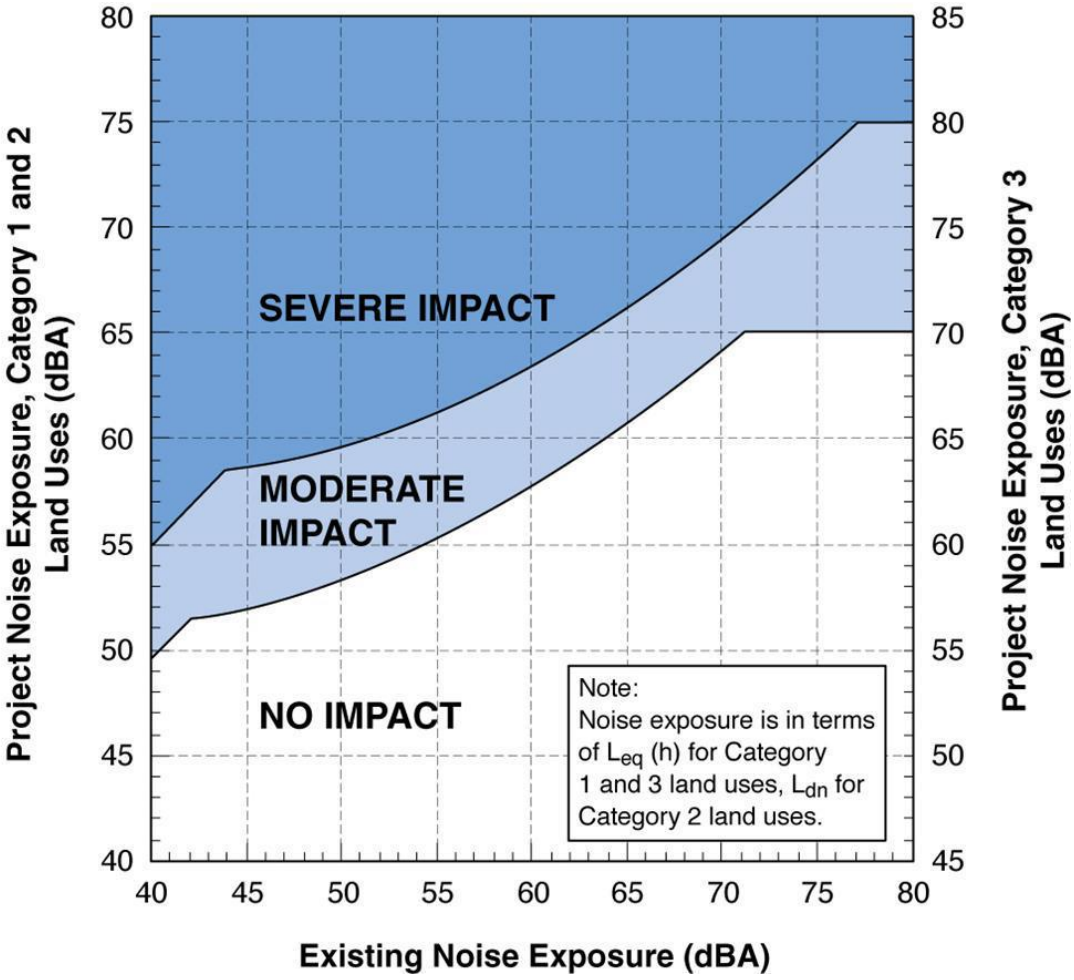
Land Use Category	Noise Metric (dBA)	Land Use Category[1, 2]
1	Outdoor $L_{eq}(h)$[3]	Tracts of land where quiet is an essential element in their intended purpose. This category includes lands set aside for serenity and quiet, and such land uses as outdoor amphitheaters and concert pavilions, as well as national historic landmarks with significant outdoor use. Also included are recording studios and concert halls.
2	Outdoor L_{dn}	Residences and buildings where people normally sleep. This category includes homes, hospitals, and hotels where a nighttime sensitivity to noise is assumed to be of utmost importance.
3	Outdoor $L_{eq}(h)$[1]	Institutional land uses with primarily daytime and evening use. This category includes schools, libraries, theaters, and churches, where it is important to avoid interference with such activities as speech, meditation, and concentration on reading material. Places for meditation or study associated with cemeteries, monuments, and museums can be considered to be in this category. Certain historical sites, parks, campgrounds, and recreational facilities are also included.

Source: FRA 2012
dBA = A-weighted decibel
$L_{eq(h)}$ = hourly equivalent sound level
[1] Parks are only considered to be noise sensitive if the park is used in a manner that is noise sensitive; active outdoor land use, for example, such as pedestrian and bike paths, are not considered noise sensitive.
[2] Historic sites and properties protected under Section 4(f) of the U.S. Department of Transportation Act and Section 106 of the National Historic Preservation Act are not intrinsically noise-sensitive; inclusion in noise-sensitive land use categories is dependent upon land use activities (e.g., if outdoor interpretation is a critical component of a historic site, then the site would be included in Category 1)
[3] L_{eq} for the noisiest hour of transit-related activity during hours of noise sensitivity.

FRA noise impact criteria for human annoyance are based on comparison of the existing outdoor noise levels and the future outdoor noise levels from a proposed HSR project. The FRA noise impact criteria specify a comparison of future with existing noise levels, not with projections of future build versus no-build noise exposure, because comparison of a projection with an existing condition is more reflective of impact than a comparison of two projections. Noise-level increases are categorized as no impact, moderate impact, or severe impact. Moderate and severe impacts are defined as follows:

- **Moderate impact—**The change in noise level is noticeable to most people but may not be sufficient to cause strong, adverse reactions from the community. Project-specific factors would be considered to determine the magnitude of impact and the need for mitigation, including the number of affected noise-sensitive sites, the existing level of noise exposure, and the costs associated with mitigation.
- **Severe impact—**Project-generated noise in the severe impact range can be expected to cause a substantial percentage of people to be highly annoyed by the new noise levels. It is FRA policy to implement noise mitigation for sensitive receptors experiencing severe impacts unless there are truly extenuating circumstances that prevent implementation.

The noise impact criteria are illustrated on Figure 4-2. The figure shows the existing noise exposure and the additional noise exposure from project operations that would cause either a moderate impact or severe impact for each land use category. The future noise exposure would be the combination of the existing noise exposure and the additional noise exposure from project operations. The equations used to calculate the impact curves are found in Section A.3.3 of the FRA guidance manual (FRA 2012).



Source: FRA 2012

FEBRUARY 2019

Figure 4-2 Noise Impact Criteria for High-Speed Rail Projects

The absolute criteria illustrated on Figure 4-2 are only applicable to new HSR sources where the existing noise levels generated by existing transit systems, roadways, and other sources would not change because of the project. The FRA criteria can also be presented in terms of relative levels for evaluating the total future noise exposure increases, or increases in cumulative noise exposure, from the project alternatives. If the existing noise is dominated by a source that would change because of the project, it would be incorrect to add the project noise to the existing noise. Therefore, the relative form of the noise criteria must be used for projects involving proposed changes to an existing rail transit system such as a shift in the location or profile of existing passenger or freight tracks or a change in the vehicle technology. Figure 4-3 illustrates the relative form of the criteria as they apply to Category 1 and 2 land uses and Figure 4-4 illustrates the criteria as they apply to Category 3 land uses. These criteria are based on the increase of the existing ambient noise level associated with project operations and can be used to evaluate the project in combination with other new planned projects (i.e., cumulative impact).

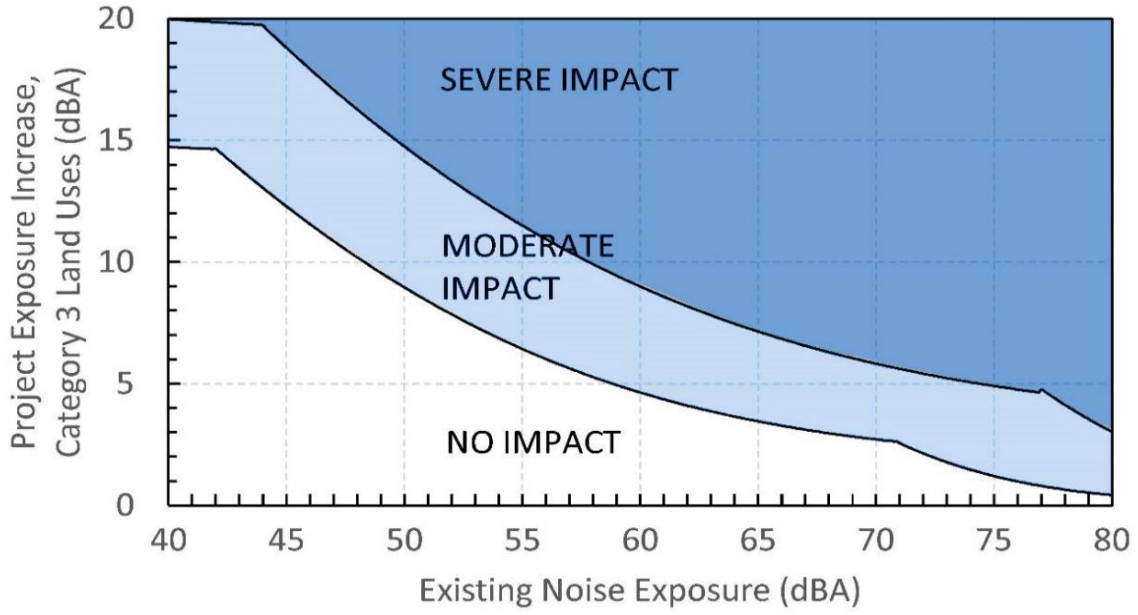
Figure 4-3 Allowable Increase in Cumulative Noise Levels (Land Use Categories 1 & 2)



Source: FRA 2012

FEBRUARY 2019

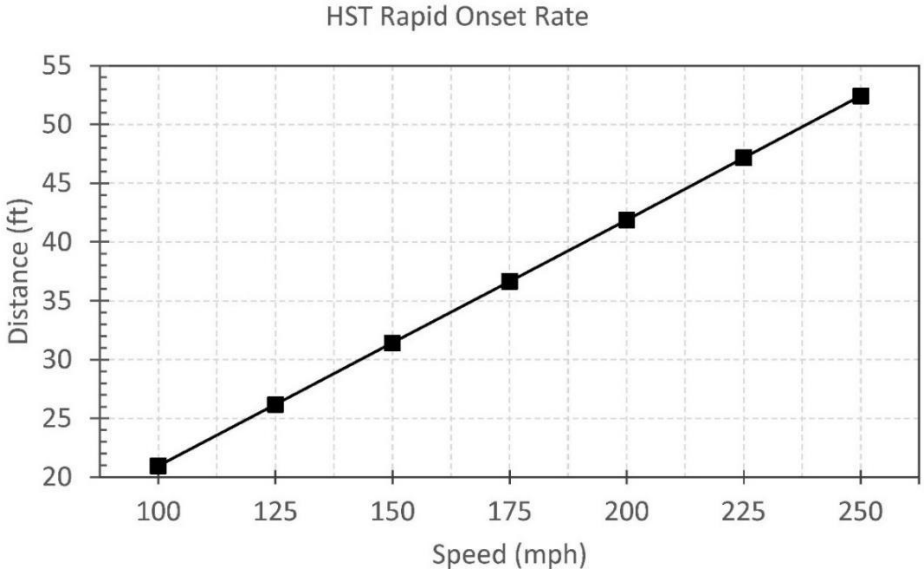
Figure 4-4 Allowable Increase in Cumulative Noise Levels (Land Use Category 3)

The noise criteria are applied at the outside of building locations at noise-sensitive areas. In some instances, the criteria apply to the building façade near doors and windows. Although noise impact is always determined based on exterior noise levels, interior noise levels may need to be evaluated when considering the need for mitigation at locations where land-use activity is solely indoors.

The process of determining impact severity begins with a determination of land use with reference to the land use categories shown in Table 4-2. Once the land use category has been determined, the appropriate noise metric (L_{dn} or L_{eq}) can be selected and used to determine the noise level and the severity of impact. The next steps are to determine the existing exterior noise exposure for each receptor or group of similar receptors and then to determine project noise exposure or the cumulative noise exposure associated with the project alternatives and other projects. Using the data on Figure 4-2 or Figures 4-3 and 4-4, the severity of impact is determined.

A hypothetical example would be to use a residential property that has an existing noise exposure of L_{dn} 60 dBA. The noise exposure resulting from the project alternatives, regional growth, and other planned projects could result in a project noise level exposure of L_{dn} 65 dBA. Adding (on a logarithmic basis) L_{dn} 65 dBA to the existing noise level would result in a total cumulative noise exposure of L_{dn} 66 dBA. This represents a potential increase of 6 dBA over the existing noise level. Using Figure 4-3, a line would be drawn vertically at 60 dBA and another line drawn horizontally at 6 dBA from left-hand axis. The intersection of these two lines determines the severity of impact. In this example, the resulting noise increase would be considered a severe impact on the residential receptor.

An additional environmental concern for HSR is the rapid rise in sound level that can occur for trains travelling at very high speeds. Under certain conditions, a rapid rise of sound level can result in a startle effect, in particular for a receptor near the tracks. The rate at which train sound levels increase is referred to as the *onset rate* and is a function of train speed and distance from the tracks. Research has found that a sudden unexpected increase in sound (a rapid onset rate) can result in greater annoyance than sounds of similar levels that vary less rapidly or are steady. When onset rates exceed about 30 dB per second people tend to be startled or surprised by the sudden onset of the sound. Consequently, analysts evaluated startle as an added annoyance factor and identified sensitive receptors that may experience a startle effect. The potential for startle as a function of train speed and distance from the train is illustrated on Figure 4-5.



Source: FRA 2012

FEBRUARY 2019

Figure 4-5 Distance from Tracks within which Startle Can Occur

The FRA guidance manual (FRA 2012) describes that the understanding of startle effects to date is partially based on using U.S. Air Force research for sudden onset of noise from aircraft. The FRA guidance describes that there are a number of unresolved issues regarding application of the U.S. Air Force research to determine the startle effects of high-speed rail, such as the

scheduled nature, lower sound levels and lower onset rates of train passbys compared to military aircraft flights. The FRA guidance states that without better definition of the application of results of noise from aircraft overflights to noise from high-speed rail passbys, it is appropriate to consider startle effects as "additional information" included in high-speed rail impact assessments as opposed to being included in the calculation of noise exposure itself. The FRA guidance does not provide a threshold in the form of an "onset rate that could be considered significant enough to cause startle on a regular basis." Thus, the 30 dB/second onset rate described above is considered indicative of when startle can occur, but is not considered a significance threshold for determining when startle would occur on a regular basis.

The FRA guidance manual (FRA 2012) also addresses potential impacts on livestock and poultry. The land use along the project corridor changes from urban and suburban to rural farmland, including some areas with livestock. Noise exposure limits for screening are shown in Table 4-4.

Table 4-4 Interim Criteria for High-Speed Rail Train Noise Effects on Livestock

Animal Category	Class	Noise Metric	Noise Level (dBA)
Domestic	Mammals (livestock)	SEL	100
	Birds (poultry)	SEL	100

dBA = A-weighted decibel
SEL = sound exposure level

4.1.4 Methods for Establishing Existing Noise Levels

Analysts established the existing noise levels throughout the noise RSA through extensive field noise measurement programs. Parsons Transportation Group conducted initial ambient noise measurements in 2010 (Authority 2011). Wilson Ihrig conducted additional measurements in 2009 and 2010 (Authority and FRA 2010a), 2013 (Wilson Ihrig 2014), and 2016 and 2017 (this analysis).

Analysts conducted long-term noise measurements (1 to 3 days in duration) to characterize the existing ambient noise in the RSA. The measurements were obtained by means of calibrated, precision, logging, sound level meters installed for a minimum of 24 hours at each location. All noise-measuring instruments used during the noise survey met ANSI S1.4-1993 specifications for Type I sound level meters. The sound level meters monitored the level of noise continuously and provided statistics on the ambient noise level for consecutive 1-hour intervals. During the monitoring period, the L_{max}, and L_{eq} values for each hour were obtained. The L_{eq} values were used to calculate the daily L_{dn} during each measured 24-hour period. For example, at a site where the measurement was conducted over a period of 3 full days, analysts calculated the average of the three hourly L_{eq} values in each hour of the day and subsequently used this to calculate an average L_{dn} at that site.

The L_{dn} describes the total noise exposure over a 24-hour period and is the noise metric FRA uses for residential (Category 2) land uses. The L_{eq} is used as the metric for evaluating noise impacts at institutional (Category 3) land uses with primarily daytime use. The hourly L_{eq} criterion is based on the daytime hour with the loudest sound level. This hour is generally referred to as the *peak-noise-hour*, which could occur at different times of the day depending on whether the noise source is from train operations or vehicular traffic. The long-term noise measurement data provided the peak-noise-hour L_{eq} for Category 3 land uses.

Analysts selected specific locations for conducting the noise measurements throughout the RSA and in a variety of settings. The selection was based on the environmental conditions expected in different areas of the communities along the alignment, the type of receptors potentially affected, the proximity of the receptors to a major arterial road or freeway, and the distance of the receptors (primarily residences) to the existing Caltrain tracks. The measurement locations where ambient noise levels were collected are representative of areas with similar environmental conditions in other areas along the HSR alignment. Areas that have primarily commercial and

industrial land uses have fewer noise-sensitive receptors and consequently fewer ambient measurement sites.

Most of the selected measurement sites would have clear line-of-sight to the HSR alignments and, therefore, are representative of receptors that are directly exposed to existing noise from Caltrain and other passenger and freight trains. To categorize the dominant existing noise sources in the RSA, analysts located some measurement sites adjacent to roadways along the alignment, some sites near existing rail sources, some sites near existing roadway sources, and some sites near both existing rail and roadway sources.

Since the existing environment is controlled by noise from conventional passenger and freight rail activity, guidance was taken from the FTA guidance manual. Analysts used the field noise measurement data to validate an existing noise spreadsheet model based on the FTA guidance manual (FTA 2018) methodology and to calculate existing ambient noise levels at all receptors. The existing noise model incorporated the known existing train (passenger and freight) operations, horn noise, and traffic noise from nearby roadways. FRA provides equivalent guidance to determine the existing ambient. (FRA 2012)

The rail noise model followed the method in Chapter 6 of the FTA guidance manual for a detailed noise analysis. Where noise measurement sites were located close to roadways, noise sources were modeled by adjusting the measured levels with distance following the procedures in Appendix D of the FTA guidance manual. In some instances, for smaller roadways, the noise model incorporated the procedures in Section 4.4 of the FTA guidance manual.

4.1.5 Prediction Methods

4.1.5.1 Construction Noise

Analysts assessed construction noise impacts according to the method described in the FRA guidance manual (FRA 2012). Construction noise estimates are always approximate because of the lack of specific information available at the time of the environmental analysis. Decisions about the procedures and equipment to be used would be made by the contractor. Project designers try to minimize constraints on how construction would be performed, and which equipment would be used to facilitate cost-effective construction. Nevertheless, estimated construction scenarios for typical railroad construction projects allow a quantitative construction noise assessment by comparing the predicted noise levels with impact criteria appropriate for the construction stage. The methods included the following data:

- Noise emissions from equipment expected to be used by contractors during typical construction activity types.
- Usage scenarios for how the equipment would be operated.
- Estimated site layouts of equipment along the right-of-way.
- Relationship of the construction operations to nearby noise-sensitive receptors.

Construction of the project would also necessitate PG&E network upgrades. The construction noise impact assessment for these upgrades follows the same methods as the typical construction noise activities discussed in Section 4.1.3.1, Construction. Analysts identified construction scenarios specific to the PG&E upgrades, along with equipment expected to be used by contractors. It is anticipated that helicopters would be used for the PG&E upgrades; therefore, the analysis specifically accounts for the noise from helicopter movements and hovering over construction sites. No annoyance penalties were applied to helicopter noise.

4.1.5.2 Operations Noise

The method used to assess operations noise impacts is consistent with the approach established in the FRA and FTA guidance manuals (FRA 2012; FTA 2018). Both guidelines provide for three levels of analysis during an environmental impact study: screening, general assessment, and detailed analysis. This analysis presents the assessment of potential noise impacts from project

operations in the adjacent communities along the project alignment following the methods for detailed analysis.

HSR Rail Traffic

HSR operations would include both revenue service trains and nonrevenue services trains with daily trips to and from the planned MOWF. Table 4-5 shows the number of HSR trains, which would be the same for all four project alternatives, from San Jose to Gilroy, from Gilroy to the planned MOWF near Gilroy, and from the MOWF to the San Joaquin Valley. The summary combines the number of daily trains in both directions of travel. Analysts conducted noise modeling for 2029 No Project, 2029 Plus Project, 2040 No Project, and 2040 Plus Project conditions. This analysis assumes that HSR service would be operational for Phase 1, which would connect San Francisco with Los Angeles via the Central Valley by 2029, and Phase 2, which would subsequently extend service to Sacramento and San Diego. The Phase 1 system analysis for the Final EIR/EIS is based on 2040 conditions. The Phase 1 build-out would be operational in 2029, and full system operations (Phase 2) would occur after the 2040 Phase 1 system operations envisioned in the Final EIR/EIS. The number of daily trains for 2029 and 2040 would be the same.

Table 4-5 Assumed 2029 and 2040 Project Operations for Noise Impact Assessment

Segment	Total Number of HSR Trains (Both Directions) - 2029			Total Number of HSR Trains (Both Directions) - 2040		
	Daytime[1]	Nighttime[2]	Peak Hour[3] (Approximate)	Daytime[1]	Nighttime[2]	Peak Hour[3] (Approximate)
Scott Boulevard to San Jose Diridon Station	40	8	4	108	26	8
San Jose Diridon Station to Gilroy Station	40	8	4	148	28	14
Gilroy Station to Gilroy MOWF	40	8	4	148	28	14
Gilroy MOWF to San Joaquin Valley	40	8	4	148	28	14

HSR = high-speed rail
MOWF = maintenance of way facility
[1] Daytime is defined as between 7:00 a.m. and 10:00 p.m.
[2] Nighttime is defined as between 10:00 p.m. and 7:00 a.m.
[3] There are six peak hours of operation per day from 6:30 AM to 9:30 AM and from 4:30 PM to 7:30 PM. There are 12 hours of nonpeak operation from 6:00 AM to 6:30 AM: 9:30 AM to 4:30 PM, and from 7:30 PM to 12:00 AM.

The specific vehicle technology proposed for the HSR system is a very high-speed (VHS) electric multiple unit (EMU) train. For the purposes of this analysis, the HSR trains are assumed to have a length of 660 feet. The various train technologies under consideration would incorporate 8 to 14 cars, with the length of each car varying to yield a train length of 660 feet.

The project's proposed maximum operation speed is 220 mph. This analysis is based on the maximum design speeds for the track throughout the Project Section. The design speeds used in the analysis were then decreased in some locations based on general operating parameters and track construction.

The noise predictions were based on the noise source reference levels in Table 5-2 of the FRA guidance manual (FRA 2012), which are shown in Table 4-6. The source reference level for VHS

EMU trains is divided into three categories or speed regimes where one sound source contributes most to the total noise level.

- Regime I: Propulsion or machinery noise
- Regime II: Mechanical noise resulting from wheel-rail interactions, guideway vibrations, or both
- Regime III: Aerodynamic noise resulting from airflow moving past the train, including the pantograph (device mounted to top of train to collect power through the overhead lines)

At train speeds up to approximately 125 mph, the propulsion noise subsource is typically the largest contributor to the total noise. The noise from the wheel-rail interface is typically dominant at speeds of 125–160 mph. Aerodynamic noise typically becomes equal to wheel-rail noise and, thus is an important component at speeds faster than 160 mph.

The noise source reference levels shown in Table 4-6 are associated with corresponding reference height, length, and speed reference terms.

Table 4-6 Federal Railroad Administration Noise Source Reference Levels for High-Speed Trains (SELs at 50 feet)

System Category and Features[1]	Example Systems	Subsource Component		Subsource Parameters		Reference Quantities			
				Length Definition, Len	Height Above Rails (feet)	SEL_{ref} (dBA)	Len_{ref} (feet)	S_{ref} (mph)	K
HS and VHS electric locomotive-hauled trains	Amtrak Acela, TGV, Eurostar, X2000, KTX-I/KTX-II, ETR 500	Propulsion		$Len_{(power)}$	12	86	73	(2)	(2)
		Wheel-rail		$Len_{(train)}$	1	91	634	90	20
		Aero	Train Nose	$Len_{(power)}$	10	89	73	180	60
			Wheel Region	$Len_{(train)}$	5	89	634	180	60
			Pantograph	(3)	15	86	(3)	180	60
		(Only include aerodynamic subsources for VHS trains above 150 mph)							
HS and VHS EMU trains	IC T, ICE 3, AVE S103, ETR450, KTX-III	Propulsion		$Len_{(power)}$	2	86	634	(2)	(2)
		Wheel-rail		$Len_{(train)}$	1	91	634	90	20
		Aero	Train Nose	$Len_{(power)}$	10	89	73	180	60
			Wheel Region	$Len_{(train)}$	5	89	634	180	60
			Pantograph	(3)	15	86	(3)	180	60
		(Only include aerodynamic subsources for VHS trains above 150 mph)							
Hs gas-turbine locomotive-hauled trains	Rohr RTL-2, Bombardier Jet-Train	Propulsion		$Len_{(power)}$	10	83	73	20	10
		Wheel-rail		$Len_{(train)}$	1	91	634	90	20

Source: FRA 2012
HS = high speed
VHS = very-high speed
EMU = electric multiple unit
SEL_{ref} = sound exposure level reference
LEN_{ref} = length reference
S_{ref} = speed reference
dBA = A-weighted decibel
mph = miles per hour
K = reference speed factor
[1] HS maximum speed 150 mph; VHS maximum speed 250 mph
[2] Source level is not adjusted for train speed
[3] Source level is not adjusted for train length

The aerodynamic subsource for a VHS EMU train is further divided by noise from the train nose region, the wheel region, and from the pantograph. The following equation from Section 5.2.2 of the FRA guidance manual (FRA 2012) is used to calculate the SEL for each of the subsources:

$$SEL = (SEL_{ref}) + 10 * Log\left(\frac{len}{len_{ref}}\right) + K * Log\left(\frac{S}{S_{ref}}\right)$$

where:

SEL	=	SEL of component subsource (dBA)
SEL_{ref}	=	Subsource reference SEL (dBA)
len	=	Subsource length (feet)
len_{ref}	=	Subsource reference length (feet)
K	=	Reference speed factor
S	=	Speed (mph)
S_{ref}	=	Reference speed (mph)

The length term in the previous equation, *len*, for the propulsion subsource is defined as the total length of the power units in the train (len_{power}), which for an EMU is the total length of all cars (660 feet). The length term for the wheel-rail noise subsource is the total length of the train (660 feet). The length term for the aerodynamic train nose subsource is the length of one car (84 feet) corresponding to an eight-car train. Because the total train length is known and the number of cars is not known, the train nose subsource component is based on the assumption of an eight-car train (corresponding to longer cars), which yields slightly higher noise levels.

Analysts used assumed HSR operating speeds provided by the design team in the noise and vibration analyses. Table 4-7 shows a summary of the range of operating speeds for each project alternative in each subsection.

Table 4-7 Assumed HSR Operating Speeds

Location	Geographic Extent	Range of HSR Operating Speeds (mph)

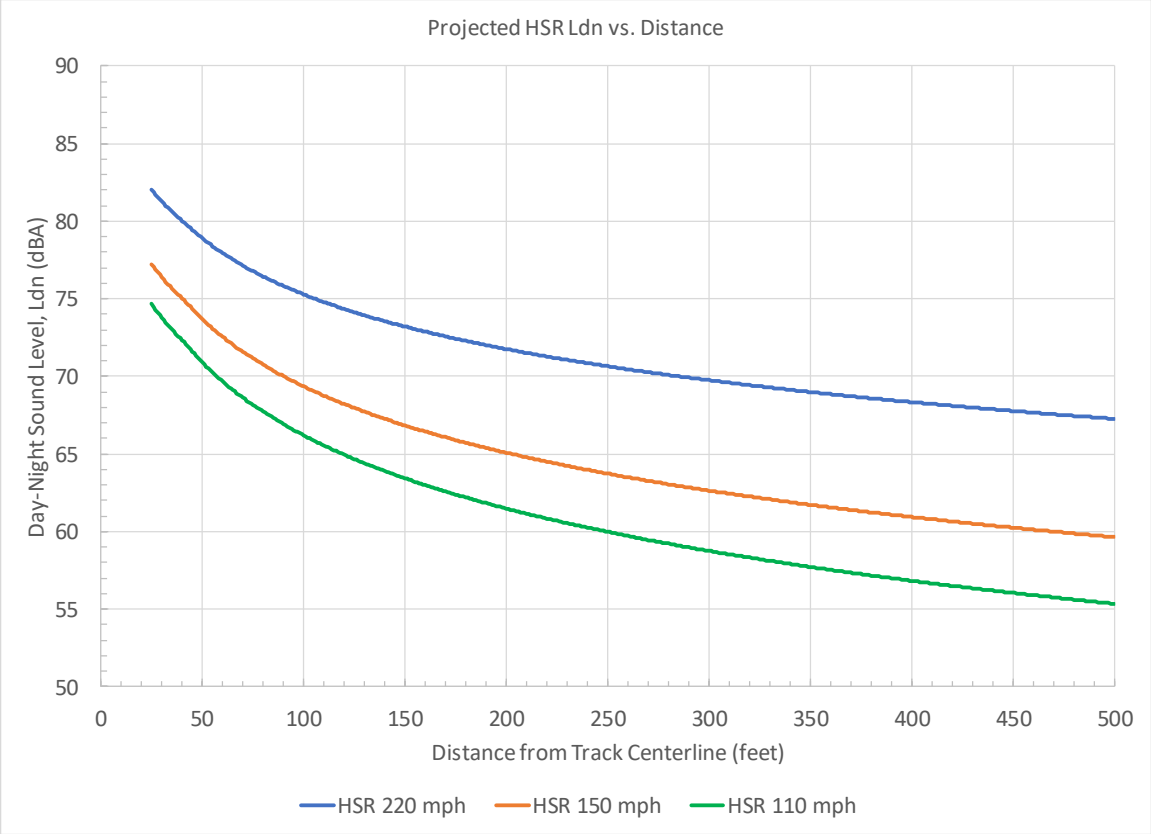
Source: Authority 2019c
HSR = high-speed rail
mph = miles per hour
[1] In this location Caltrain would use the same tracks as HSR with Alternative 4 and operate at the same speeds.

The predictions account for the proposed operations schedule, ground propagation attenuation effects, cross-sectional geometry of the guideway and superstructure (e.g., elevated guideway), and shielding provided by existing noise barriers and intervening rows of buildings. Analysts assumed all tracks were ballast-and-tie construction with concrete ties, except in tunnels where concrete slab track would be used. The project includes sections of track on embankment with the top-of-rail height approximately 10 to 15 feet above adjacent ground. Many sections of track

would be on aerial structures with the top-of-rail height approximately 50 feet above grade and a maximum height of approximately 85 feet above grade. The aerial structure guideway would incorporate a solid parapet on both outer edges approximately 3 feet higher than the top-of-rail. In many locations, the parapet would provide significant acoustical shielding from the propulsion and wheel-rail noise subsources, reducing sound levels. The noise predictions assume that the parapet would be included for all aerial structure sections of track. Alternative 4 would include blended HSR service with Caltrain on at-grade tracks.

Figure 4-6 illustrates the projected 24-hour noise levels from project operations versus distance at train speeds of 220 mph, 150 mph, and 110 mph. The data for the 220 mph and 150 mph speeds are representative of a typical embankment section of track between San Jose and Gilroy. The data for 110 mph are representative of a typical at-grade section of track between San Jose and Gilroy. The figure shows that L_{dn} from HSR operating at 220 mph is typically from 5 to 8 dB higher than when HSR is operating at 150 mph. The figure further illustrates how the noise levels from project operations would attenuate to typical L_{dn} at various distances from the track.



FEBRUARY 2019

Figure 4-6 Projected HSR 24-Hour Noise Levels versus Distance for Typical Embankment Track Section without Shielding Effects

Adjustments were made to predicted noise levels to account for increases in localized noise because of special trackwork, such as crossovers or turnouts. Alternatives 1, 2, and 3 would use special trackwork, such as moveable-point frogs, to avoid significant gaps in the rail running surface. Any insulated joints would be low-impact joints. Therefore, any increases in localized noise because of special trackwork with Alternatives 1, 2, and 3 are expected to be small and would not change overall effects on sensitive receptors. Alternative 4 would use the same type of

special trackwork as currently exists in the corridor. All special trackwork frogs in the Project Section for Alternative 4 were assumed to be standard frogs.

Other Rail Traffic

The noise analyses for the 2029 and 2040 conditions include noise-level changes associated with future Caltrain operations between San Jose and Gilroy. The Caltrain Peninsula Corridor Electrification Project (PCEP) will replace approximately 75 percent of the current train fleet, which currently consists of diesel locomotive-hauled coaches, with EMU trains between San Francisco and Tamien Station in San Jose by 2029, and 100 percent by 2040. The PCEP will also increase service to six Caltrain trains per peak hour north of Tamien. An environmental impact analysis for the PCEP was prepared in 2014. The details of the analysis are contained in the *Caltrain Peninsula Corridor Electrification Project Noise and Vibration Technical Report* (Wilson Ihrig 2014). The changes to Caltrain service will change the existing noise environment in the RSA; therefore, the PCEP is included as part of these analyses.

Under Alternatives 1, 2, and 3, Caltrain operations between Tamien and Gilroy would use only diesel locomotive-hauled coaches. Under Alternative 4, however, the blended HSR service would require that all Caltrain tracks from San Jose to Gilroy be upgraded to operate both HSR and Caltrain PCEP up to 110 mph. Therefore, under Alternative 4, Caltrain would operate EMU trains from San Jose to Gilroy, and the total Caltrain daily trips would increase from 6 to 8 trains per day.

Similar to the wayside noise projections for HSR, the noise predictions for Caltrain operations were based on the source reference levels and account for the proposed operations schedule, ground effect, cross-sectional geometries, the existing shielding of noise barriers, and intervening rows of buildings where applicable.

Existing freight operations were also included in the analysis, and future freight operations were included in the cumulative noise analysis. Freight operations occur mainly during the nighttime. Noise from freight operations was modeled based on FTA methods. Future freight operations in the future conditions 2029 and 2040 were determined based on growth factors and were used in the cumulative noise impact analysis. Freight train speeds were assumed to match existing speeds between San Jose and Gilroy.

Other passenger train services in the RSA were incorporated into the analyses, including the Altamont Corridor Express train, Amtrak Capital Corridor, and Coast Starlight passenger train service. Two planned new passenger services—the Coast Daylight and the Transportation Agency for Monterey County Salinas Rail Extension—were included in the future cumulative analyses as well as the Bay Area Rapid Transit (BART) Silicon Valley Santa Clara Extension. Caltrain accounts for the majority of the existing rail traffic along most of the Project Section, followed by ACE, freight, and Amtrak Coast Starlight (up to two trains per day). Other passenger train speeds were assumed to match existing speeds in the RSA. Table 4-8 shows the existing daily train operations, Table 4-9 shows the projected daily 2029 train operations, and Table 4-10 shows the projected daily 2040 train operations in the Project Section.

Horn Noise

Future HSR tracks would predominately follow existing rail tracks between San Jose and Gilroy. These existing rail tracks include numerous at-grade crossings where Caltrain, freight, and other passenger service trains are currently required to sound their warning horns. Additionally, trains currently sound horns while approaching Caltrain passenger station platforms. Table 4-11 shows all the locations in the Project Section where trains currently sound warning horns. The table also shows the locations where Caltrain, freight, and other passenger trains would sound horns in the future with the project alternatives. An *X* in the table indicates that those trains do sound horns in those locations.

Under Alternatives 1, 2, and 3, HSR trains would not sound horns at any at-grade crossings in the RSA because the HSR tracks would be grade separated. Under Alternative 4, HSR trains would sound horns as they approach at-grade crossings and Caltrain passenger stations.

To assess noise levels associated with the at-grade crossings and horn-sounding locations for each project alternative, the noise predictions include a horn noise model. The horn noise model was based on the FRA horn noise model (FRA 2000) and field noise measurements. Analysts applied the model to receptors within 0.25 mile of each at-grade crossing and passenger station

location where horns must be sounded. Noise measurements in the RSA and in the adjacent San Francisco to San Jose Project Section indicate that the maximum sound level from Caltrain and other passenger trains are 96 dBA at a distance of 100 feet from the track. This is consistent with the minimum horn sound level allowable by FRA regulations to provide adequate warning of the train approach and is used by existing Caltrain locomotives and future Caltrain EMUs with PCEP.

The noise prediction model for freight train horns was based on a maximum sound level of 107 dBA at 100 feet from the track. This assumption is based on field measurement data by FRA showing that this is the average horn noise level from freight trains (FRA 2018). The noise prediction model for HSR train horns assumes a maximum sound level of 96 dBA at 100 feet from the track, consistent with Caltrain and FRA regulations. Crossing bells near existing at-grade crossings were included in the noise measurement program, and were modeled based on the methods in the FTA guidance manual (FTA 2018).

The mounting height location of train horns is also an important input to the noise modeling results, because the horn height affects the amount of ground attenuation and shielding provided by noise barriers. The height of the horns on existing Caltrain locomotives is modeled at 16 feet above-top-of-rail (ATOR). Future Caltrain EMUs will incorporate a lower mounted horn height of 3 feet ATOR. Horns on all freight trains and other passenger trains, including Amtrak and Ace, are located at a height of 16 feet ATOR. Future HSR trains will have horns mounted at a height of 7 feet ATOR.

HSR = high-speed rail
Alt = alternative
[1] Caltrain trains, other passenger trains, and freight trains sound horns at existing Caltrain stations in addition to sounding horns approaching at-grade crossings.

Annoyance from Rapid Onset of HSR Passbys

There is considerable evidence that increased annoyance is likely to occur for train noise events with high travel speeds (rapid onset rates) (FRA 2012). A rapid rise of sound level can result in a startle effect, particularly for a noise-sensitive receptor near the tracks. Analysts assessed the potential for annoyance from rapid onset based on HSR train speed and distance of the receptor from the track. Figure 4-5 on page 4-8 illustrates the relationship of speed and distance to locations where the onset rate for project operations may cause a startle effect.

Other Noise Sources

Station Noise

Analysts assessed noise impacts associated with the planned HSR stations in San Jose and Gilroy at each nearby noise-sensitive receptor by following the method for detailed noise analysis for HSR train operations summarized in Section 5.2 of the FRA guidance manual (FRA 2012) and the method for a general noise assessment for parking facilities summarized in Section 4.4 of the FTA guidance manual (FTA 2018).

The dominant noise source at the stations would be HSR train movements. The station noise analysis includes noise measurements at representative clusters of receptors near the stations, noise modeling to determine existing ambient noise conditions, and predictions of future noise conditions. The noise predictions at these receptors are based on the project operations noise levels, incorporating the type of train equipment to be used, train schedules, train consists (number of cars), speed profiles (including through trains), and track elevation.

Analysts used the station plan layouts and number of planned parking spaces to predict the noise exposure from the parking facilities at nearby noise-sensitive receptors. The FTA guidance manual (FTA 2018) Section 4.4 reference SEL of 92 dBA corresponding to 1,000 cars in a peak activity hour was used to predict the additional noise from the parking lots at each of the HSR stations.

Analysts tabulated the predicted noise levels from HSR trains at the stations and from the parking facilities along with the existing ambient noise exposures at the identified receptors or clusters of receptors. Levels of impact (no impact, moderate impact, or severe impact) were determined by comparing the existing and projected noise exposure based on the impact criteria described in Section 4.1.3.

Maintenance Facility Noise

Noise sources at the MOWF near Gilroy are expected to include daily inspections, pre-departure cleaning and testing, quarterly inspections, and train storage activities. Analysts used the method in Section 4.4 of the FTA guidance manual (FTA 2018) to predict noise exposure from the maintenance facility. A reference SEL of 118 dBA corresponding to 20 train movements in a peak activity hour was used to predict noise from the facility. The planned MOWF layouts and number of movements per day were used to calculate noise exposure at nearby noise-sensitive

receptors. The predicted noise levels from the MOWF were combined with the project operations noise predictions and compared to the impact criteria described in Section 4.1.3.

Vehicle Traffic Noise

In addition to noise from project operations, noise from changes in traffic volume due to the project was considered for 2029 and 2040 conditions. Analysts assessed the anticipated increases in noise levels resulting from increased traffic volumes near the HSR stations and maintenance facilities. Total daily traffic volumes for roadway segments near the HSR stations and maintenance facilities were calculated for each project alternative and were compared to existing traffic volumes.

Analysts used the following methods to determine locations with the potential for noise impacts from traffic:

- Where major roads would undergo changes due to the project alternatives, traffic growth factors for road segments were calculated to assess locations where the change in traffic volume would increase noise levels. Increases with and without the project were calculated separately.
- Traffic growth factors for road segments near HSR stations and MOWFs were calculated to assess locations where the change in traffic volume would increase noise levels. Increases with and without the project were calculated.
- For each project alternative, roadway segments were identified where the growth factors indicated a potential increase in noise of 3 dB or greater, which represents a noticeable increase in noise level.
- At locations where the growth factors for a project alternative resulted in a 3 dB or greater increase in noise, for instance, a doubling of traffic, an analysis was conducted to determine what portion of the increase in traffic volume would be related to the alternative.

Daily traffic volumes for these roadway segments were used to calculate traffic growth factors to assess the potential change in noise levels for each project alternative. Analysts calculated the potential noise level increase for each roadway segment by comparing the future traffic volume with the project alternatives to the existing volume and the future volume without the alternatives. The comparison to existing traffic volume is consistent with the FRA approach to assessing operations noise impacts. The increases with the alternatives over the projected future volumes without the alternatives are caused by the project. Increases in future traffic volumes without the project alternatives over the existing traffic volumes would be due to other growth factors not related to HSR.

The potential change in noise level for each roadway segment is calculated as follows:

$$\Delta = 10 * Log\left(\frac{a}{b}\right)$$

where:

Δ	=	Change in noise level (dBA) due to the project alternatives
a	=	Future average daily traffic (ADT) traffic volume with project alternatives
b	=	Existing ADT traffic volume *or* Future ADT traffic volume without project alternatives

Traction Power Substation Noise

In addition to the noise generated by project operations, impacts may be caused by some of the electrical traction power substations (TPSS) and facilities. TPSSs would be located at approximately 30-mile intervals and would include two 115/50 kV or 230/50 kV single-phase transformers at 60 megavolt amperes (MVA). The traction power switching stations would be required midway between the TPSSs and would include two (10 to 60 MVA) transformers. Traction power paralleling stations would be required at approximately 5-mile intervals between

the traction power switching stations and the TPSSs. Each traction power paralleling station would include one or two (10 to 60 MVA) transformers.

The FRA does not have its own analysis techniques because these facilities are not unique to high-speed systems, and they reference the FTA method. Thus, FTA reference levels were used to calculate the total project noise level at the receivers identified within the screening distances of 250 feet for facilities with no intervening buildings and 150 feet for the configurations where intervening buildings would shield traction power facilities (TPF) noise from noise sensitive receptors. The FTA reference SEL for substations is 99 dBA at 50 feet, which equates to an L_{dn} of 70 dBA at 50 feet (assuming continuous 24-hour usage).

Benchmark Tests to Validate HSR Noise Prediction Model

The Authority developed a protocol to validate HSR noise models for accurate HSR noise predictions and consistency among the multiple project sections. The *Benchmark Tests for Calibration of CAHST Noise Models* (May 26, 2010) (Authority and FRA 2010b) establishes a series of test cases and input parameters that practitioners use to validate individual noise models. The purpose is to make sure that the HSR noise models used by practitioners for each of the project sections throughout California agree and achieve consistent prediction results.

The test cases established by the Authority include calculations at two speeds (100 mph and 200 mph) for receptors at multiple distances and elevations for the project on typical embankment and aerial guideway locations. Input parameters include train vehicle type, length of train, number of trains during daytime and nighttime, as well as specific geometrical track configurations.

The results of the benchmark tests are shown in Table 4-12 and Table 4-13. The results agree with the HSR benchmark noise prediction model results and are consistent with the Authority's established noise model.

4.2 Vibration

4.2.1 Descriptors

Ground vibration is an oscillatory motion of the soil with respect to the equilibrium position and can be quantified in terms of displacement, velocity, or acceleration. Vibration can be described by its peak or root-mean-square (RMS) amplitudes. The RMS amplitude is useful for assessing human annoyance, while peak vibration is most often used for assessing the potential for damage to building structures. Building damage is often discussed in terms of peak velocity, or peak particle velocity (PPV). Construction vibration is assessed in terms of PPV.

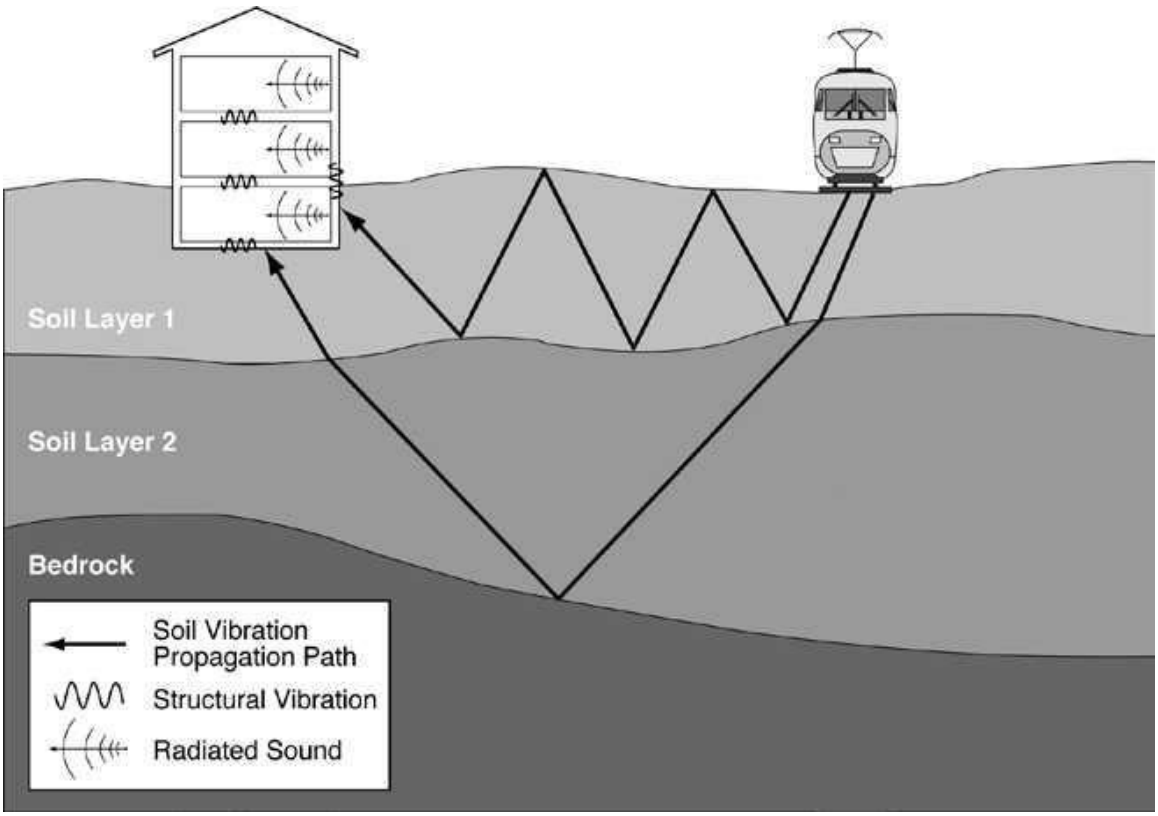
Although vibration velocity can be quantified in units of inches per second, it is common to use the velocity level to quantify vibration to cover the wide range of magnitudes that can be encountered. The vibration is expressed in terms of the velocity level (L_v) in decibel units, defined as:

$$Lv = 20 * Log(\frac{v}{v_{ref}})$$

Where, "v" is the RMS velocity amplitude and "v_{ref}" is the reference velocity amplitude (1 micro-inch per second [µin/sec]). Thus, the descriptor used to assess ground-borne vibration is L_v in vibration decibels (VdB). Like noise, VdB is related to a reference quantity; in this case, 1 micro-inch per second. Vibration is a function of the frequency of motion measured in Hz. Ground vibration of concern for transportation sources generally spans from 4 to 160 Hz. The overall vibration is the combined energy of ground motion at all frequencies, and this overall vibration level is used in this analysis.

Vibration attenuates as a function of the distance between the source and the receptor because of geometric spreading and inherent damping in the soil that absorbs energy of the ground motion. Ground-borne vibration from rapid transit systems is caused by dynamic forces at the wheel/rail interface. It is influenced by many factors, which include the rail and wheel roughness, out-of-round wheel conditions, the mass and stiffness of the rail vehicle truck and its suspension components, the mass and stiffness characteristics of the track support system, and the local soil conditions.

Vibration transmitted through the transit structure, such as at-grade ballast and tie track, radiates energy into the adjacent soil in the form of different types of waves that propagate through the various soil and rock strata to the foundation of nearby buildings. Buildings respond differently to ground vibration depending on the type of foundation, the mass of the building, and the building interaction with the soil. Once inside the building, vibration propagates throughout the building with some attenuation with distance from the foundation, but often with amplification due to floor resonances. The basic concepts for rail system-generated ground vibration are illustrated on Figure 4-7.



Source: FRA 2012 FEBRUARY 2019

Figure 4-7 Propagation of Ground-Borne Vibration into Buildings

Figure 4-8 illustrates the typical levels of human response and, at much higher levels, the structural response to ground-borne vibration. The figure shows that the threshold of human perception is about 65 VdB, while the threshold for cosmetic damage is about 100 VdB. However, the threshold for building damage is directly related to the condition of the structure. It is very rare that transportation-generated ground vibration approaches building damage levels.

Ground-borne noise is a secondary phenomenon of ground-borne vibration. When a building structure vibrates, noise is radiated into the interior of the building. Typically, this low- frequency sound would be perceived as a low rumble. The magnitude of the sound depends on the frequency characteristic of the vibration and the manner in which the room surfaces in the building radiate sound. Ground-borne noise is quantified by the A-weighted sound level inside the building.

Figure 4-8 Typical Levels of Ground-Borne Vibration and Response to Vibration

4.2.2 Resource Study Area

The vibration RSA extends 275 feet from the project alternatives' centerlines, which is narrower than the noise RSA. This distance is consistent with the FRA screening procedures and was established to identify where vibration impacts from HSR might occur. Table 4-14 shows the FRA-recommended screening distances for vibration assessments of various land use types. To include all potentially affected areas along the project extent, the highest speed and frequent event categories were used to establish screening distances.

Table 4-14 FRA-Recommended Screening Distances for Vibration Assessments

Land Use	Train Frequency[1]	Screening Distance (feet from centerline) Train Speed[2]	
		100 to 200 mph	200 to 300 mph
Residential	Frequent	220	275
	Infrequent	100	140
Institutional	Frequent	160	220
	Infrequent	70	100

Source: FRA 2012
mph = miles per hour
[1] Frequent = more than 70 passbys per day; Infrequent = fewer than 70 passbys per day
[2] Screening distances are not provided for speeds of less than 100 mph, as train speeds would typically exceed 100 mph.

4.2.3 Impact Criteria

4.2.3.1 Construction

The construction vibration assessment is based on the FRA guidance manual (FRA 2012). To avoid temporary annoyances to building occupants or interference with vibration-sensitive equipment inside special-use buildings during construction, FRA recommends using the long-term operations vibration criteria for a general assessment. These are discussed in Section 4.2.3.2, Operations.

Table 4-15 shows the FRA guideline for vibration damage criteria from construction activity. The table provides PPV limits for four building categories. Analysts used a crest factor of 4 (representing a PPV–RMS difference of 12 VdB) to calculate the approximate RMS vibration velocity limits in VdB from the PPV limits. These limits were used to identify areas that should be addressed during engineering design of the project alternatives.

Table 4-15 Construction Vibration Damage Criteria

Building Category	PPV (in/sec)	Approximate L_v[1]
I. Reinforced-concrete, steel, or timber (no plaster)	0.5	102
II. Engineered concrete and masonry (no plaster)	0.3	98
III. Nonengineered timber and masonry buildings	0.2	94
IV. Buildings extremely susceptible to vibration damage	0.12	90

Source: FRA 2012
PPV= peak particle velocity
in/sec = inches per second
L_v = velocity level
RMS = root-mean squared
VdB = vibration decibels
µin/sec = microinch per second
[1] RMS VdB re: 1 µin/sec

4.2.3.2 Operations

Vibration impact levels are determined by the receptor land-use category and the daily number of the vibration events. The limits are based on the maximum RMS vibration level. The impact level also depends on the type of analysis being conducted (i.e., ground-borne vibration or ground-borne noise).

The FRA provides guidelines to assess the human response to different levels of ground-borne noise and vibration as shown in Table 4-16. Ground-borne noise and vibration levels represent the vibration during a train passby (RMS vibration level of an event). The guidelines provide

additional criteria for special-use buildings that are sensitive to ground-borne noise and vibration as shown in Table 4-17.

The criteria in Table 4-16 and Table 4-17 apply only to occupied spaces in potentially affected buildings (i.e., receptors). The number of daily train events are considered in determining which criterion to apply. HSR service would provide more than 70 trains per day, which would be characterized as frequent events. Ground-borne vibration is assessed at the building façade. Ground-borne noise is assessed inside buildings.

In most cases, for at-grade or aerial train operations, the airborne noise would be substantially louder than the ground-borne noise, and ground-borne noise is not perceived separately from the airborne noise. Therefore, the analysis focused on airborne noise to assess at-grade or aerial portions; ground-borne noise was used to assess tunnels.

Table 4-16 Ground-Borne Vibration and Ground-Borne Noise Impact Criteria for General Assessment

Land Use Category	GBV Impact Levels (VdB re: 1 µin/sec)			GBN Impact Levels (dB re: 20 µPa)		
	Frequent Events[1]	Occasional Events[2]	Infrequent Events[3]	Frequent Events[1]	Occasional Events[2]	Infrequent Events[3]
Category 1: Buildings where vibration would interfere with interior operations.	65 VdB[4]	65 VdB[4]	65 VdB[4]	N/A[5]	N/A[5]	N/A[5]
Category 2: Residences and buildings where people normally sleep.	72 VdB	75 VdB	80 VdB	35 dBA	38 dBA	43 dBA
Category 3: Institutional land uses with primarily daytime use.	75 VdB	78 VdB	83 VdB	40 dBA	43 dBA	48 dBA

Source: FRA 2012
GBV = ground-borne vibration
GBN = ground-borne noise
VdB = vibration decibels
µin/sec = microinch per second
dB = decibel
µPa = micro-Pascal
dBA = A-weighted decibel
N/A = not applicable
[1] *Frequent Events* is defined as more than 70 vibration events of the same kind per day.
[2] *Occasional Events* is defined as between 30 and 70 vibration events of the same kind per day.
[3] *Infrequent Events* is defined as fewer than 30 vibration events of the same kind per day.
[4] This criterion limit is based on levels that are acceptable for most moderately sensitive equipment such as optical microscopes. Vibration-sensitive manufacturing or research requires detailed evaluation to define the acceptable vibration levels. Ensuring lower vibration levels in a building often requires special design of the HVAC systems and stiffened or vibration-isolated floors.
[5] Vibration-sensitive equipment is not sensitive to ground-borne noise.

Table 4-17 Ground-Borne Vibration and Ground-Borne Noise Impact Criteria for Special Buildings

Land Use Category	GBV Impact Levels (VdB re: 1 µin/sec)		GBN Impact Levels (dB re: 20 µPa)	
	Frequent Events[1]	Infrequent Events[2]	Frequent Events[1]	Infrequent Events[2]
Concert halls	65 VdB	65 VdB	25 dBA	25 dBA
TV studios	65 VdB	65 VdB	25 dBA	25 dBA
Recording studios	65 VdB	65 VdB	25 dBA	25 dBA
Auditoriums	72 VdB	80 VdB	30 dBA	38 dBA
Theaters	72 VdB	80 VdB	35 dBA	43 dBA

Source: FRA 2012
[1] *Frequent Events* is defined as more than 70 vibration events per day.
[2] *Occasional or Infrequent Events* is defined as fewer than 70 vibration events per day.
GBV = ground-borne vibration
GBN = ground-borne noise
VdB = vibration decibels
µin/sec = microinch per second
dB = decibel
µPa = micro-Pascal
dBA = A-weighted decibel

Analysts applied additional vibration impact criteria where the project would be located in an existing rail corridor from San Jose to Gilroy. When there are existing substantial sources of vibration, such as trains, at locations affected by the project, the existing vibration levels were factored into the assessment. The FRA provides guidance on how to apply the vibration impact criteria based on the existing vibration conditions. The existing rail corridor is first defined by how many trains are on it per day. The following scenarios summarize the FRA guidance and a flow chart graphically summarizes the evaluation process (Figure 4-9):

- **Infrequently used rail corridor** (fewer than five trains per day):
  - Compare the vibration levels from the project to the vibration criteria in Table 4-16 and Table 4-17. If the vibration levels from the project exceed the criteria in Table 4-16 and Table 4-17, the project would have a vibration impact.
- **Moderately used rail corridor** (5 to 12 trains per day):
  - If the existing train vibration levels exceed the criteria in Table 4-16 and Table 4-17 and the project vibration levels are at least 5 VdB lower than the existing levels, the project would not have a vibration impact.
  - If the existing train vibration levels exceed the criteria in Table 4-16 and Table 4-17 and the project vibration levels are within 5 VdB of the existing levels, then compare the vibration levels from the project to the vibration criteria in Table 4-16 and Table 4-17.
  - If the existing train vibration levels do not exceed the criteria in Table 4-16 and Table 4-17, then compare the vibration levels from the project to the vibration criteria in Table 4-16 and Table 4-17. If the vibration levels from the project exceed the criteria in Table 4-16 and Table 4-17, the project would have a vibration impact.
- **Heavily used rail corridor** (more than 12 trains per day):
  - If the existing train vibration levels exceed the criteria in Table 4-16 and Table 4-17 and the project would cause a substantial increase in the total number of trains per day, the project would have a vibration impact. (A substantial increase is defined as approximately doubling the total number of trains per day.)

  - If there is not a substantial increase in the number of vibration events per day, the existing train vibration levels exceed the criteria in Table 4-16 and Table 4-17, and the project vibration levels are 3 VdB greater than the existing levels, the project would have a vibration impact.
  - If the vibration levels from the project are 5 VdB greater than the existing levels, then the existing source can be ignored, and the vibration levels from the project should be compared to the criteria in Table 4-16 and Table 4-17. If the vibration levels from the project exceed the criteria in Table 4-16 and Table 4-17, the project would have a vibration impact.

- **Moving existing tracks:**
  - Existing vibration can be substantial when an HSR project would share an existing rail right-of-way and shift the location of existing tracks. The relocated track can result in lower vibration levels from the existing trains at some locations and higher vibration levels at other locations.
  - If the vibration levels from the relocated existing trains would create higher levels, then the vibration levels from the relocated existing trains and from the project must be compared to the criteria in Table 4-16 and Table 4-17.
  - If the existing vibration levels prior to relocating the track did not exceed the criteria in Table 4-16 and Table 4-17, then the vibration levels from the relocated track must be compared to the criteria in Table 4-16 and Table 4-17. If the vibration levels from either the relocated existing trains or from the project exceed the criteria in Table 4-16 and Table 4-17, the project would have a vibration impact.
  - If the existing vibration levels prior to shifting the track exceeded the criteria in Table 4-16 and Table 4-17 and the vibration levels from the relocated track would increase by more than 3 VdB, then the project would have a vibration impact.

The vibration levels from the new project vibration source must also be compared separately to the criteria in Table 4-16 and Table 4-17.

The RSA includes portions of all of the previously noted situations because of the number of Caltrain, freight, and other passenger trains that travel the existing corridor daily. The corridor from Scott Boulevard to West Alma Avenue in San Jose is a heavily used rail corridor with a segment of new rail corridor between Diridon Station and Tamien outside the existing rail right-of-way (Alternatives 1, 2, 3, and 4). From West Alma Avenue in San Jose to 10th Street in Gilroy, the project would follow the existing rail right-of-way, in a moderately used rail corridor (Alternatives 1, 2, 3, and 4). The Morgan Hill Bypass would introduce a new rail corridor (Alternatives 1 and 3). The alignment through downtown Gilroy from 10th Street to the Santa Clara County line is an infrequently used rail corridor (Alternatives 1, 2, and 4). The alignment located east of Gilroy is a new rail corridor (Alternative 3). The corridor from south of the Santa Clara County line through Pacheco Pass and the San Joaquin Valley is a new rail corridor (Alternatives 1, 2, 3, and 4).

In addition to the criteria provided for general assessment purposes, FRA has established criteria in terms of 1/3-octave band frequency spectra for use in detailed analyses. Figure 4-10 illustrates the application of these criteria and Table 4-18 shows descriptions of the criteria. The VC-A through VC-E curves are used for special equipment that is very sensitive to vibration. Four vibration-sensitive facilities with sensitive equipment were identified in the vibration RSA.

Figure 4-10 FRA Criteria for Detailed Vibration Analysis

Table 4-18 Interpretation of Vibration Criteria for Detailed Analysis

Criterion Curve	Maximum Vibration Level (VdB re: 1 µin/sec)[1]	Description of Use
Workshop	90	Distinctly perceptible vibration. Appropriate to workshops and non-sensitive areas.
Office	84	Perceptible vibration. Appropriate to offices and non-sensitive areas.
Residential Day	78	Barely perceptible vibration. Adequate for computer equipment and low-power optical microscopes (up to ×20).
Residential night, operating rooms	72	Vibration not perceptible, but ground-borne noise may be audible inside quiet rooms. Suitable for medium-power optical microscopes (×100) and other equipment of low sensitivity.
VC-A	66	Adequate for medium- to high-power optical microscopes (×400), microbalances, optical balances, and similar specialized equipment.
VC-B	60	Adequate for high-power optical microscopes (×1,000), inspection and lithography equipment to 3-micron line widths.
VC-C	54	Appropriate for most lithography and inspection equipment to 1-micron detail size.
VC-D	48	Suitable in most instances for the most demanding equipment, including electron microscopes operating to the limits of their capability.
VC-E	42	The most demanding criterion for extremely vibration-sensitive equipment.

VC = vibration criteria
VdB = vibration decibels
µin/sec = microinch per second

4.2.4 Methods for Establishing Existing Vibration Levels

Locations for measuring the existing ground vibration levels in the RSA encompass the variable conditions along the HSR alignment. The primary source of existing ground vibration in the RSA is Caltrain operations and to a lesser degree other passenger rail and infrequent freight trains. Analysts selected measurement sites by project alternative to measure the overall ground vibration level due to train passbys as well as the spectral (frequency content of the ground vibration) components of the passby vibration, which are influenced by the local soil conditions and input forces unique to different types of trains. The selection of the vibration measurement sites was also based on a preliminary vibration analysis conducted for the project in 2011 (Authority 2011), which was based on the FRA General Assessment method as described in Section 8.2 of the FRA guidance manual (FRA 2012). The selection of measurement sites for this work prioritized those areas with higher potential for vibration impact.

Because Caltrain train vibration is the dominant existing source of ground vibration in most areas, the vibration survey focused on obtaining ground vibration measurements during Caltrain passbys. Vibration was measured for sensitive receptors at typical setback distances from the nearest track. For each site, train vibration was typically measured at two distances from the rail alignment simultaneously.

The ambient vibration survey establishes the existing overall vibration levels throughout the corridor. The variation in measured vibration levels from Caltrain trains in the RSA is due to the varying speed and the variability in the soil vibration attenuation characteristics. These factors

were used in the selection of field vibration propagation testing locations which for the detailed analysis.

Section 4.2.5.2, Operations Vibration, provides details about the vibration propagation measurement procedure.

4.2.5 Prediction Methods

4.2.5.1 Construction Vibration

Analysts assessed construction vibration impacts in accordance with the method described in Chapter 10 of the FRA guidance manual (FRA 2012) for quantitative construction vibration assessments. HSR construction activity scenarios were developed to estimate construction vibration quantitatively, comparing the predicted ground-borne vibration amplitudes with appropriate construction stage impact criteria. Quantitative construction vibration analysis was conducted where there was a potential for pile driving, vibratory compaction, demolition, or excavation near vibration-sensitive structures. Criteria for annoyance (Tables 4-16 and 4-17) and damage (Table 4-15) were applied to determine impacts from construction vibration. Analysts used the following information to assess the construction vibration:

- Vibration source levels from equipment expected to be used by contractors.
- Estimated site layouts of equipment along the right-of-way.
- Distance from the construction operations to nearby vibration-sensitive receptors.

4.2.5.2 Operations Vibration

The FRA guidance manual (FRA 2012) provides three levels of analysis: screening, general assessment, and detailed analysis. The screening analysis was used to determine the RSA for conducting the detailed analysis of operations vibration. For this analysis, analysts evaluated residential locations within 275 feet and institutional locations within 220 feet of the alternatives' centerlines.

The FRA criteria for assessing ground-borne vibration from shared corridors require that the levels resulting from the relocated existing tracks be compared to the existing vibration levels. Thus, analysts prepared separate analyses to predict ground-borne vibration from project operations and from existing and future Caltrain operations.

The FRA prediction method is based on an empirical modeling approach. The basis of the empirical model is the assumption that vibration generated by a train rolling on steel rail and its propagation through the surrounding geologic strata (soil and rock) and into buildings can be separated into independent elements. Each of the vibration elements can be quantified separately by measurements conducted in the field. The individual elements are combined to predict ground-borne noise and vibration inside occupied buildings, which are vibration-sensitive and adjacent to the rail alignment. Adjustments are made to the prediction model to account for other factors such as train speed and track and superstructure effects.

The prediction model for ground-borne vibration employs the following equation:

$$Lv = FDL + LSR + AF$$

where:

Lv	=	projected vibration velocity level in a specific building: VdB
FDL	=	force density level: dB re: 1 lb/ft$^{1/2}$
LSR	=	line source response: dB re: 10^{-6} (inch/sec)/(lb/ft$^{1/2}$)
AF	=	adjustment factor for track and structure: dB (relative level)

All of the model parameters are determined in terms of their 1/3-octave band frequency content. The overall vibration level at a specific building is the combination of the individual 1/3-octave band levels determined by an "energy sum" over all the bands. The energy sum, calculated by summing the energy in all 1/3-octave bands, results in a single-number level (also in decibels: VdB) accounting for the vibration energy in all of the 1/3-octave bands within the overall frequency range of interest. The FRA general assessment vibration criteria are based on the overall vibration level. The FRA detailed assessment criteria are based on the individual 1/3-octave band levels.

Each projection of ground-borne vibration begins with the force density level (FDL), which represents an excitation force caused by the wheels of a train rolling on the rail. As each train has several wheels rolling simultaneously, the prediction model incorporates this input as an incoherent line of vibration forces generated by the dynamic interaction of the rail vehicle and the rail and the track support system. This analysis uses the FDL indicated for the Pendolino train as the most representative FDL for the technology envisioned for the statewide HSR system because it is also a high-speed EMU vehicle.

The FDLs used in the vibration analyses are illustrated on Figure 4-11. The Pendolino FDL used to predict HSR vibration levels is shown at a reference speed of 150 mph. The FDL of Caltrain locomotives is also illustrated on Figure 4-11 at a reference speed of 50 mph. The Caltrain FDL was calculated from field measurements of existing trains in the Project Section and the San Francisco to San Jose Project Section. The figure shows that even at very different speeds, the HSR and Caltrain FDLs are similar below 31.5 Hz. The Caltrain FDL shows a peak at 100 Hz that is more than 10 dB greater than the HSR FDL, which would result in higher vibration levels in the 100 Hz 1/3-octave band.

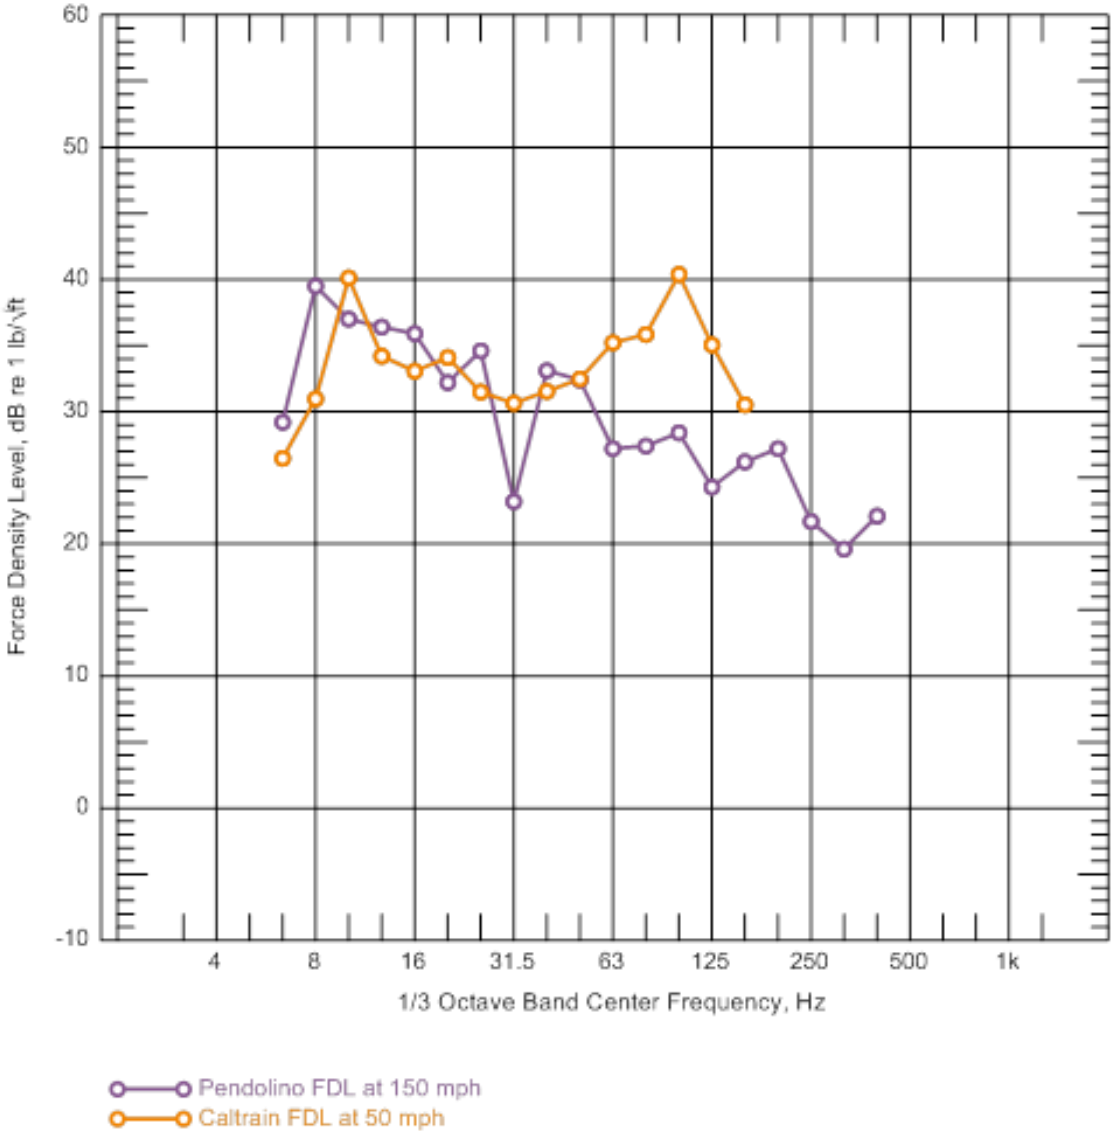
The reference HSR Pendolino FDL is from a system where high-speed passenger trains were operating on their own dedicated tracks, with smooth rail in good condition. The HSR trains in the Project Section would operate on tracks that are shared with both Caltrain and freight trains, which increases the likelihood that the rail roughness could increase with time and potentially lead to increased vibration levels. To account for this, an added engineering factor of 5 VdB was added to the HSR vibration predictions where blended service would occur under Alternative 4. The FDL of the Caltrain system (locomotives and coaches) was empirically derived from train passby measurements and the impact testing performed at multiple sites throughout the Project Section and in the San Francisco to San Jose Project Section. The future Caltrain rolling stock will be EMU vehicles (no locomotive). The FTA guidelines provide an FDL for commuter rail; however, this assumes the use of a locomotive. Consideration was given to other previously measured FDLs that might approximate an FDL for an EMU, including FDL for heavy rail transit vehicles. However, none was found to be completely satisfactory. Consistent with the *Caltrain Peninsula Corridor Electrification Project Noise and Vibration Technical Report* (Wilson Ihrig 2014), the FDL for the existing Caltrain was selected with the assumption that the EMU would be no greater than the existing FDL.

Figure 4-11 illustrates the FDL spectra used in the vibration prediction model for HSR and Caltrain. The FDLs for HSR and Caltrain were adjusted for speed using the following formula.

$$20 * Log(S/Sref)$$

where:

S = operations speed (mph)
S_{ref} = speed reference (mph)



FEBRUARY 2019

Figure 4-11 Force Density Level Spectra Used in the Vibration Analysis

The second element in the FRA model is the line source response (LSR). The LSR quantifies the effect of soil conditions at a receptor location relative to the FDL. The LSR represents the response of the local soil strata to vibration and the attenuation of vibration energy due to its propagation through the surrounding soil. The LSR characterizes the vibration velocity response at a single location on the surface of the ground due to incoherent forces distributed over the length of a train (i.e., a finite line source). LSR as used in this analysis refers to the response of a free ground surface and not to the response of a built structure, such as a floor in a building. However, the response of an individual building can be measured if there are only a limited number of buildings potentially affected. This analysis addresses impacts on hundreds of buildings, making that approach impractical.

The LSR for a soil region is found by imparting a vertical force on the ground surface or bottom of a borehole for a subsurface alignment, measuring that force with a load cell or strain gage and simultaneously measuring the vertical vibration velocity of the ground surface at several distances

from the impact location. This procedure, described in the FRA guidance manual (FRA 2012), provides a set of point source responses (also referred to as transfer mobility), from which an LSR can be constructed.

The LSR is added to the FDL to obtain the ground surface vibration velocity levels in the absence of buildings. Analysts obtained the various LSRs used in the vibration analyses from numerous site measurements conducted in the field using the procedure described in the FRA guidance manual.

The normal procedure for obtaining transfer mobility data is to impact the ground at several locations and measure the ground surface velocity at various distances from the point of impact. For surface alignments, analysts used a pneumatic, force-instrumented hammer to generate impact forces. The pneumatic hammer consists of a 27-pound cylindrical mass guided by a 4-inch diameter tube with pneumatic assist to both raise the hammer and drive the hammer downward onto a load cell. Approximately 20 to 30 impacts are recorded at each surface position.

For subway alignments, boreholes were drilled and a force-instrumented transducer was attached to the end of a drill string. The impacts delivered to the bottom of the borehole were obtained with a standard, 130-pound driller's slide hammer. Force input from the hammer and geophone responses are recorded simultaneously for 40 to 50 impacts at each testing depth. A graphic representation of the surface test is illustrated on Figure 4-12 and the borehole test is illustrated on Figure 4-13.

Transfer mobility data collected by the vibration testing were then fit with polynomial functions of distance using least squares regression. The point source responses that are derived from the curve fitting were then numerically integrated over a length of 600 feet (to approximate the train length) to obtain the following mathematical function for the line source response with distance:

$$LSR(d) = A + B * Log(d) + C * Log^2(d)$$

where:

A, B, C	=	polynomial coefficients
d	=	perpendicular and horizontal distance from track centerline (feet)

Because ground-borne noise and vibration are typically not substantial at distances of more than 250 feet from the tracks, a 600-foot train length provides a reasonable approximation to the length of train that would affect ground-borne vibration.

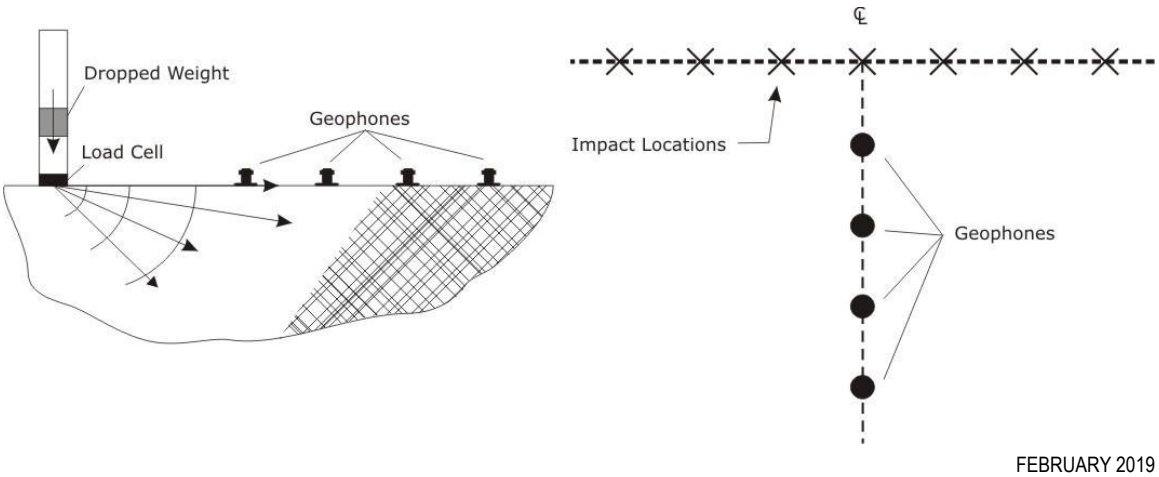


Figure 4-12 Surface Vibration Propagation Test (cross section)

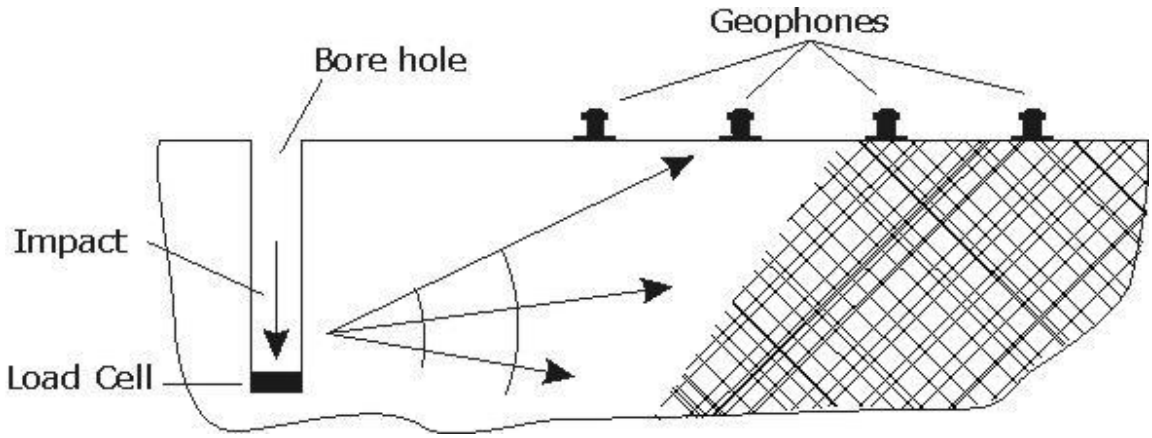

FEBRUARY 2019

Figure 4-13 Borehole Vibration Propagation Test (cross section)

To predict levels of ground-borne noise and vibration for project conditions different from those on which the FDL is based, analysts applied the adjustment factors specified in the FRA guidance manual (FRA 2012) to account for the effects of train speed and the specific alignment structures (e.g., at grade, embankment, aerial, and tunnel geometry). Vibration levels from HSR on an aerial structure are assumed 10 VdB less than vibration from at-grade or embankment sections of track based on Table 8-2 of the FRA guidance manual.

Ground-borne noise is generated when the surfaces of interior building elements such as floors, walls, and ceilings vibrate because of ground-borne vibration from trains. Ground-borne noise is commonly described as the “rumble” from a subway train. The prediction of such noise is directly related to the prediction of vibration inside a building.

The final step in the ground-borne noise and vibration prediction procedure is the prediction of interior noise levels in occupied building spaces due to acoustic radiation caused by the room’s vibrating elements. The following equation from Section 9.3.2 of the FRA guidance manual shows the relationship between ground-borne vibration and ground-borne noise:

$$L_A = L_v + K_{rad} + K_{A-wt}$$

where:

L_A	=	A-weighted sound level in 1/3 octave band (dBA re: 20 µPa)
L_v	=	RMS vibration velocity level in 1/3 octave band (VdB re: 1 µin/sec)
K_{rad}	=	adjustment to convert from vibration to sound pressure level and account for average acoustical absorption inside room (typically -5 dB for residential rooms)
K_{A-wt}	=	A-weighting adjustment in each 1/3 octave-band

Ground-borne noise is computed on a 1/3 octave-band basis. The 1/3 octave-band noise levels are A-weighted and combined to obtain an overall A-weighted noise level. The A-weighted ground-borne noise level is evaluated with respect to the FRA ground-borne noise criteria.

Where trains change tracks or cross over other tracks, wheel impacts at regular crossovers (conventional rail-bound manganese frogs) or special trackwork produce an increase in vibration relative to standard track and thus would require an adjustment factor to account for the ground vibration levels in the immediate vicinity of a track crossover or turnout. Adjustments were made to predicted vibration levels to account for increases in localized vibration due to special trackwork, such as crossovers or turnouts.

Alternatives 1, 2, and 3 would use special trackwork without significant gaps in the rail running surface, such as moveable-point frogs. Moveable-point frogs reduce noise and vibration because the wing rail closes the gap at the frog, reducing the impact as the wheel crosses it. Any insulated joints would be low-impact type joints. Therefore, any increases in localized vibration because of special trackwork are expected to be small and would not change overall effects on sensitive receptors.

Under Alternative 4, HSR trains would operate in blended service on the Caltrain tracks between San Jose and Gilroy and would use the same type of special trackwork currently in use in the corridor. All special trackwork frogs under Alternative 4 are assumed to be standard frogs. Wheel impacts at turnouts and crossovers with standard frogs were assumed to cause localized increases in vibration of up to 10 VdB within 50 feet, then decreasing with distance from the frogs.

5 EXISTING CONDITIONS AND EFFECTS ANALYSIS

This chapter presents the existing noise and vibration environment and existing measurement results. This chapter also provides the results of the noise and vibration impact assessments for construction and operations.

5.1 Noise

5.1.1 Existing Noise Environment

This section summarizes the noise measurement results and describes the noise-sensitive land uses in the RSA. Section 5.1.1.2, Noise Measurement and Modeling, summarizes the existing noise model used to identify the existing ambient noise conditions at all noise-sensitive receptors in the RSA.

5.1.1.1 Noise Measurement Results

A total of 65 measurements of ambient noise were conducted in the noise and vibration RSA. Measurements of ambient noise were conducted at 11 locations in the San Jose Diridon Approach Subsection between Scott Boulevard and West Alma Avenue, 10 locations in the Monterey Corridor Subsection between West Alma Avenue and Bernal Way, 36 locations in the Morgan Hill and Gilroy Subsection between Bernal Way and State Route (SR) 152, 2 locations in the Pacheco Pass Subsection between SR 152 and Interstate (I-) 5, and 6 locations in the San Joaquin Valley Subsection between I-5 and Carlucci Road. The long-term measurement locations are illustrated on Figures 5-1 through 5-5. Photographs of the noise measurement sites are provided in Appendix A.

The noise monitors were located at or near noise-sensitive locations. At some sites the noise measurement microphones were located in the back, front, or side yards of residences. At other sites, the microphones were mounted to utility poles near noise-sensitive locations. At all sites, the microphones were positioned in accordance with FRA guidance relative to both the dominant ambient noise sources and the noise-sensitive locations.

FEBRUARY 2019

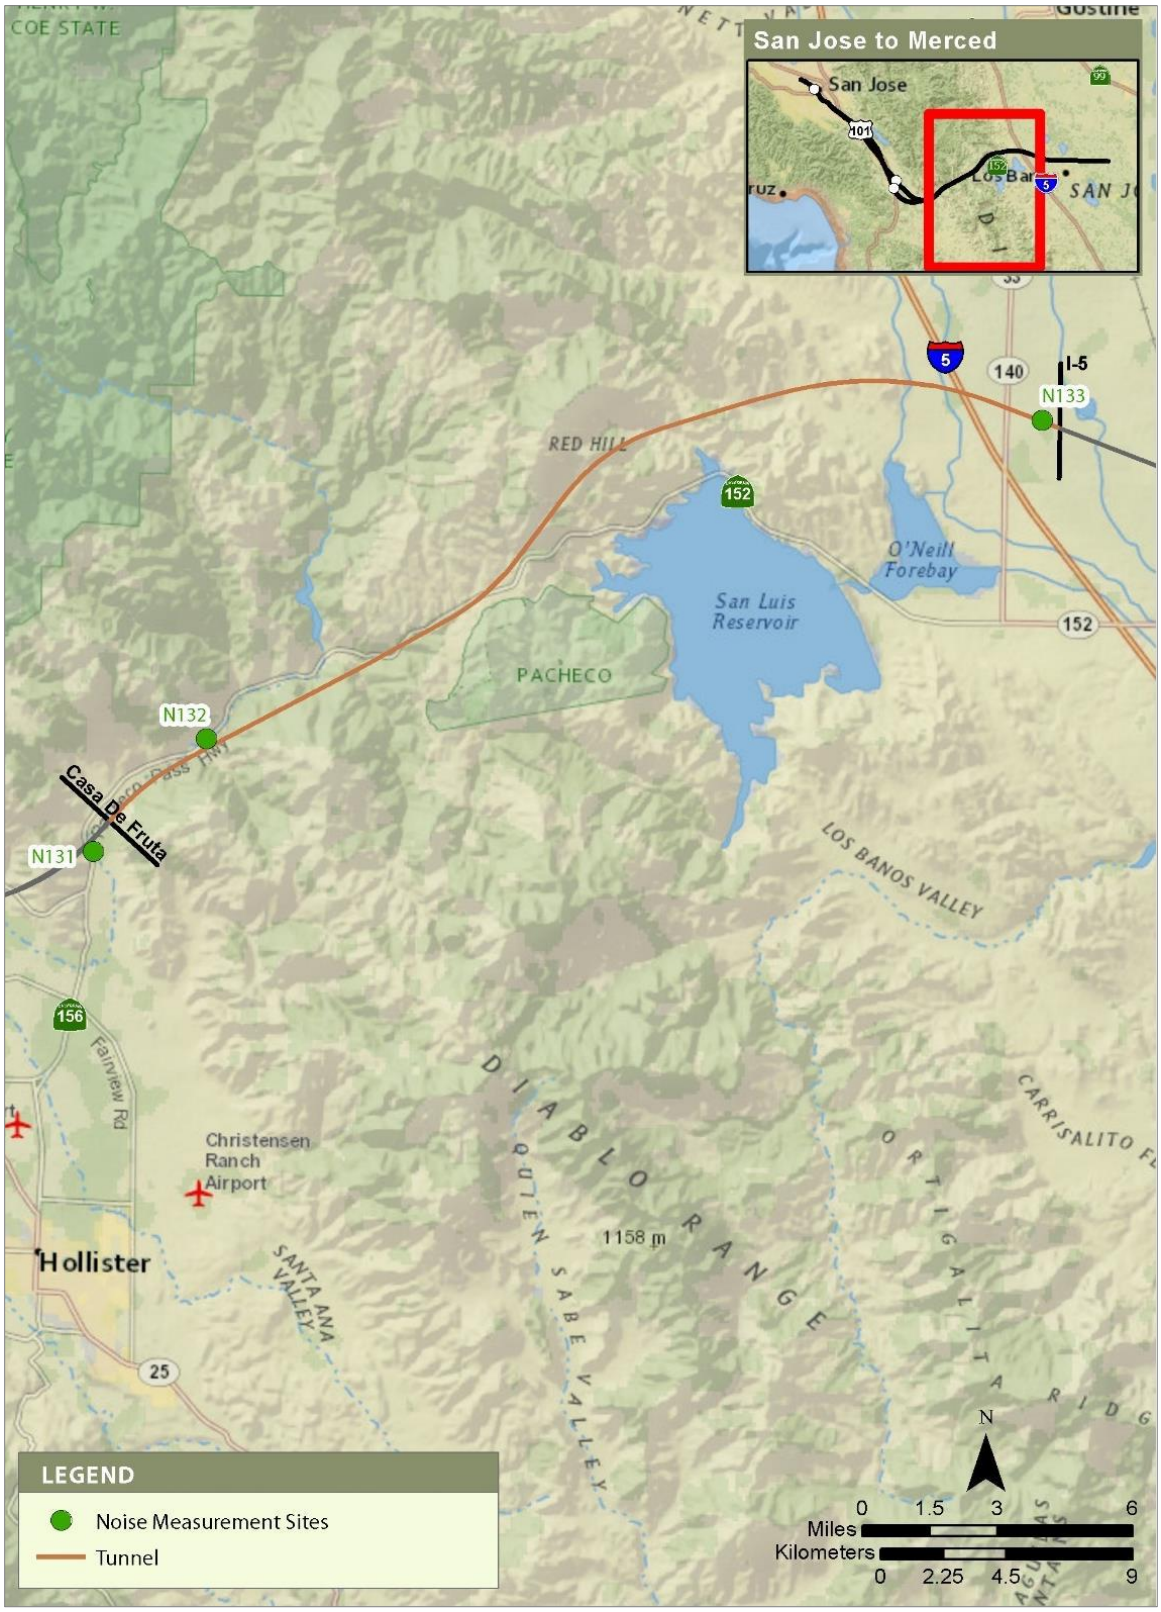
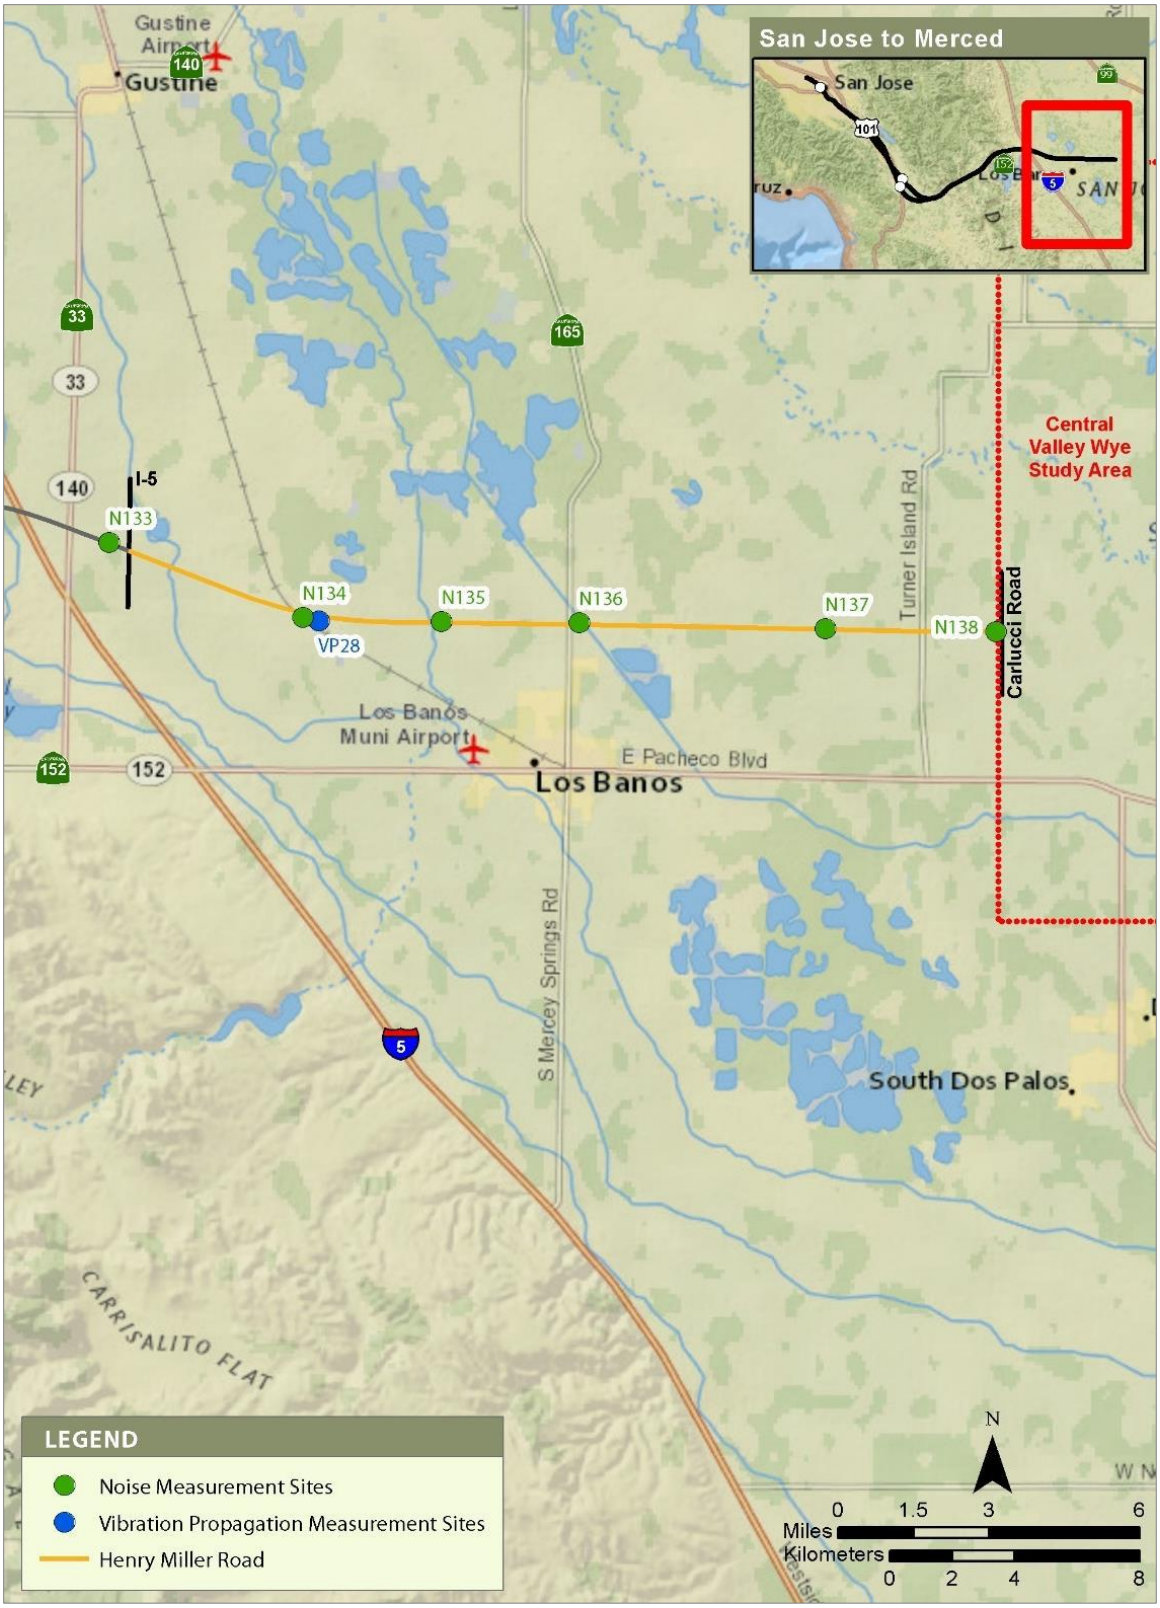
Figure 5-3 Noise and Vibration Measurement Locations



FEBRUARY 2019

Figure 5-4 Noise and Vibration Measurement Locations



FEBRUARY 2019

Figure 5-5 Noise and Vibration Measurement Locations

The major noise sources for much of the project are trains in the existing rail corridor. In some locations, the project alternatives would deviate from the existing rail corridors and pass through rural areas. In some areas, the project alternatives would follow major highways where the existing noise environment is dominated by traffic noise. Noise monitors were located near noise-sensitive receptors and near existing major noise sources, such as roadways or rail lines. The noise measurement results shown in Table 5-1 represent the actual measured sound levels at the noise monitor locations. The results of the existing noise measurement program were used to validate the existing noise spreadsheet model developed by Wilson Ihrig to better predict existing noise levels at all noise-sensitive locations throughout the RSA. The existing noise spreadsheet model was used to identify the ambient existing noise levels at the exterior façade of building locations for residential land uses and at the nearest point of use for nonresidential noise-sensitive sites.

Commercial and industrial uses are the largest developed component in the northern portion of the San Jose Diridon Station Approach Subsection, with increasing residential use south of West Alma Avenue. South of San Jose Diridon Station, the alignment would pass through primarily residential areas but also some areas of commercial and industrial use to a point just north of Morgan Hill (near Kirby Avenue). In downtown Gilroy, dense urban commercial and residential uses are on both sides of the alignment. South and east of Gilroy, the primary land use is agricultural, interspersed with small rural communities and scattered residences on large acreages. The land uses east of Gilroy are predominantly agricultural and open space, with limited residential development and a commercial outlets center near Leavesley Road. The land use through the Pacheco Pass Subsection, where the alignment would pass through a new 13.5-mile tunnel, is open space and rangeland. Where the alignment would exit the tunnel in the eastern portion of the Pacheco Pass Subsection and then crosses I-5, residential and local commercial uses in the community of Santa Nella are located south of the alignment. The land uses in the San Joaquin Valley Subsection, along Henry Miller Road, are primarily agricultural (with supporting structures such as silos and barns) with scattered residences.

The noise measurement results are organized by subsection in Table 5-1. Table 5-1 shows the results of the ambient noise measurements conducted in 2010 by Parsons Transportation Group and ambient noise measurements conducted in 2009, 2010, 2013, 2016, and 2017 by Wilson Ihrig. Noise measurements conducted by Parsons Transportation Group are included in the *San Jose to Merced Section Noise and Vibration Technical Report* (Authority 2011). Noise measurements conducted by Wilson Ihrig in 2009 and 2010 are included in the *San Francisco to San Jose Section Noise and Vibration Technical Report* (Authority and FRA 2010a). Noise measurements conducted by Wilson Ihrig in 2013 are included in the *Caltrain Peninsula Corridor Electrification Project Noise and Vibration Technical Report* (Wilson Ihrig 2014). Noise measurements conducted by Wilson Ihrig in 2016 and 2017 are included in this assessment. Appendix B provides plots of the ambient noise measurement results.

Table 5-1 Ambient Noise Measurement Results

[2] Includes existing noise from nearby airport

San Jose Diridon Station Approach Subsection

In San Jose, the noise RSA follows the Caltrain right-of-way through moderately dense urban areas with mixed land use. North of San Jose Diridon Station, the land use on the east side of the existing rail alignment is primarily industrial, while the western side is mainly residential. The closest residences are approximately 30 to 50 feet from the existing railway. Bellarmine College Preparatory School campus is on the western side of the RSA. The closest Bellarmine school buildings are more than 350 feet from the existing railway line.[8] At San Jose Diridon Station, there are multifamily buildings along the entire west side of San Jose Diridon Station facing the existing tracks and platforms. Templo La Hermosa church is on the eastern side of the station, beyond the parking lots approximately 550 feet from the station.

South of San Jose Diridon Station, land uses in the noise RSA include transportation rights-of-way associated with I-280 and SR 87, residential neighborhoods, and some commercial/industrial areas. The San Jose Fire Department Bureau of Field Operations campus is located just south of San Jose Diridon Station on the east side of the RSA. Gardner Elementary School is located approximately 275 feet south of I-280 on the south side of the RSA.

Existing noise in this portion of the RSA is dominated by a number of daily rail operations that share the alignment (Table 4-8). This alignment is a heavily used rail corridor with 92 daily weekday Caltrain passenger trains currently operating between San Francisco and San Jose Diridon Station. Forty daily Caltrain trains operate through to Tamien Station. Approximately two to nine freight trains run along the route per day. Fourteen Capital Corridor and eight ACE trains run along the alignment daily between De La Cruz Boulevard and San Jose Diridon Station. ACE trains continue to travel south to Tamien Station to access the layover facility. Amtrak Coast Starlight trains pass through the section twice daily. Santa Clara VTA light rail trains run along the center of SR 87. Other noise sources include traffic on I-880, SR 87, I-280, local roads, as well as aircraft activities associated with Norman Y Mineta San Jose International Airport.

[8] Outdoor sports fields associated with Bellarmine are adjacent to the existing railway, but are not considered noise-sensitive uses by the FRA guidance manual (FRA 2012).

Ambient noise conditions were characterized at eleven locations: N76 to N84 and N139 and 140. The ambient L_{dn} in the San Jose Diridon Station Approach Subsection ranged from 61 dBA to 82 dBA, depending on the location.

Monterey Corridor Subsection

South of West Alma Avenue, the noise RSA extends along SR 87 until south of Almaden Expressway, where it turns east toward Monterey Road following the Union Pacific Railroad (UPRR) right-of-way. Land uses along the Monterey Corridor Subsection include primarily single-family residential neighborhoods and some commercial/industrial areas. Toward the southern end of the subsection, land uses include scattered single-family homes and farms.

The closest residence is approximately 30 feet from the existing railway line, near Skyway Drive, where backyards of single-family homes abut the right-of-way. An Elk's Lodge on West Alma Avenue is approximately 180 feet from SR 87 on the west side of the RSA. A recording studio is on the east side of the RSA, although it is approximately 350 feet from the existing railway and behind some intervening commercial buildings. The School of the Blues music school is on Monterey Road, approximately 190 feet from the existing railway line. Other institutional land uses include Edenvale Branch Library and four places of worship.

Sources of existing noise include traffic on SR 87, Monterey Road (near Capitol Caltrain Station), SR 85, and local roads, as well as the existing rail traffic. South of Tamien Station the daily rail traffic consists of six Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day. VTA light rail trains also run along the center of SR 87.

Ambient noise conditions were characterized at 10 locations: N85 to N94. The ambient L_{dn} in the Monterey Corridor Subsection ranged from 61 dBA to 79 dBA, depending on the location.

Morgan Hill and Gilroy Subsection

In this subsection, the noise RSA diverges to follow the different horizontal alignments. It is best characterized by separate discussion of the portion of the RSA along Monterey Road through downtown Gilroy, the portion of the RSA adjacent to U.S. Highway (US) 101 through Morgan Hill, and the portion of the RSA through east Gilroy.

Along Monterey Road through Downtown Gilroy

The noise RSA extends along the single UPRR track from Bernal Way into downtown Gilroy. It continues past the Gilroy Caltrain Station, along UPRR south of downtown, and then turns east toward the Pacheco Pass Highway near Bloomfield Avenue. Land uses include farms with scattered single-family homes, and residential neighborhoods and commercial areas in Morgan Hill and San Martin. The closest residences to the existing railway line are a row of single-family homes approximately 40 feet away, where backyards abut the right-of-way, between Bernal Way and Metcalf Road. Three hotels are within 200 feet of the existing railway line. The closest school is approximately 145 feet from the existing railway line. The closest place of worship is approximately 150 feet from the existing railway line. In downtown Morgan Hill, the Morgan Hill Community Center outdoor amphitheater is approximately 500 feet from the existing railway line and the South Valley Civic Theatre and Community Playhouse is more than 600 feet from the railway line.

In the downtown Gilroy area, land uses include a mix of residential neighborhoods and commercial/industrial areas. South of downtown, land uses include farms with scattered single-family homes. The closest residential building to the existing railway line is approximately 50 feet from UPRR track on Monterey Road and Lewis Street. The closest school is Gilroy Preparatory School, which is approximately 145 feet from the existing railway line. Pintello Comedy Theater is approximately 365 feet from the existing railway line and the District Theater Live Music Venue is 50 feet from the railway line.

Sources of existing noise include traffic on Monterey Road and local roads, as well as the rail traffic along UPRR consisting of six Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day. Caltrain trains stop at the existing Gilroy station, which is

a terminal station. Amtrak and freight trains continue to operate south of Gilroy. Farming and industrial activities south of Metcalf Road also contribute to existing noise levels, as do aircraft activities associated with South County Airport and Frazier Lake Airpark

Ambient noise conditions were characterized at 24 locations in the portion of the RSA along Monterey Road through downtown Gilroy: N95 to N101, N103, N104, N106, N108, N111, N113 to 115, N118, N120 to N122, N124 to N126, N129, and N130. The ambient L_{dn} along this portion of the Morgan Hill and Gilroy Subsection ranged from 56 dBA to 81 dBA, depending on the location.

Adjacent to US 101 through Morgan Hill

Land uses include farms with scattered single-family homes, and residential neighborhoods and commercial areas in Morgan Hill near El Camino Real/US 101.

For most of this noise RSA, the noise environment is dominated by US 101 and local street traffic. At connection points on both ends, some receptors are exposed to the rail traffic along UPRR (six Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day). Farming activities south of Morgan Hill also contribute to existing noise levels.

Ambient noise conditions were characterized at six locations: N102, N105, N107, N109, N110, and N112. The ambient L_{dn} along this portion of the Morgan Hill and Gilroy Subsection ranged from 57 dBA to 70 dBA, depending on the location.

East Gilroy

Land uses include farms with scattered single-family homes. For most of this RSA, the noise environment is dominated by rural traffic. At the connection point, some receptors are exposed to the rail traffic along UPRR (six Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day). Other noise sources include aircraft activities associated with Frazier Lake Airpark and farming activities.

Ambient noise conditions were characterized at six locations: N116, N117, N119, N123, N127, and N128. The ambient L_{dn} along this portion of the Morgan Hill and Gilroy Subsection ranged from 56 dBA to 82 dBA, depending on the location.

Pacheco Pass Subsection

Land uses in this subsection are quite different from the rest of the project extent. There are some sparsely scattered single-family homes, but much of the subsection is not inhabited. The RSA passes through two portions of the Cottonwood Creek Wildlife Area.

For most of this RSA, the noise environment is dominated by SR 152 and rural traffic. The majority of the alignment in this subsection is in a tunnel. Ambient noise conditions were characterized at two locations where the alignment is above grade: N131 and N132. The ambient L_{dn} along this subsection ranged from 58 dBA to 82 dBA, depending on the location.

San Joaquin Valley Subsection

The RSA passes Santa Nella Road/I-5 then follows Henry Miller Road to Carlucci Road. Land uses include farms with scattered single-family homes and one elementary school.

For most of the San Joaquin Valley Section, there are no existing rail noise sources and the noise environment is dominated by rural traffic. In Volta, a freight railroad line crosses the RSA. One single-family residence is within 200 feet of the freight railway line. Sources of existing noise include traffic along Henry Miller Road and other local roadways as well as farming activities.

Ambient noise conditions were characterized at six locations: N133 to N138. The ambient L_{dn} along this subsection ranged from 65 dBA to 79 dBA, depending on the location.

5.1.1.2 Noise Measurement and Modeling Discussion

To validate the existing noise model, the existing noise spreadsheet model results were calculated at the exact locations of the noise monitors. In some instances, the noise monitors were closer to existing noise sources such as roadways and rail lines than the noise-sensitive

buildings themselves. Once the existing noise model was validated for existing conditions by showing close agreement with the measurement results (as shown in Table 5-2), the existing noise model was then used to predict ambient noise levels at all sensitive receptors, typically building facades, in the project extent.

Table 5-2 shows the results of the comparison of the existing noise model and the measured noise levels at the measurement locations. The comparison indicates that the existing noise model is in close agreement with the field noise measurement data. The data were within 3 dB at all but one measurement location (N137). Site N137 was located along Henry Miller Road in the San Joaquin Valley Subsection. Four noise measurement sites were along Henry Miller Road. The existing noise model for receptors in that area incorporated the measurement results from all four sites. Some variation of measured noise levels along Henry Miller Road was due to daily fluctuations in traffic, as would be expected.

dBA = A-weighted decibel
L_{dn} = day-night sound level
[1] The L_{dn} was calculated from the average hourly L_{eq} values collected over the entire measurement period.
[2] The difference is the measured level minus the modeled level at each location.

5.1.2 Noise Impact Assessment

Noise impacts were assessed according to the criteria described in Section 4.1.3 and the method, data, and assumptions described in Section 4.1.4, Methods for Establishing Existing Noise Levels, and Section 4.1.5, Prediction Methods.

5.1.2.1 Construction Noise Impacts

Temporary noise and vibration impacts would result from activities associated with the construction of new tracks and stations, utility relocation, grading, excavation, track work, demolition, and installation of systems components. Impacts may occur in residential areas and at other noise-sensitive land uses within several hundred feet of the alignment. The potential for noise impacts would be greatest near pavement breaking and close to any nighttime construction work. Construction noise varies with the process used, layout of the sites, and the type and condition of the equipment used. The noisiest pieces of equipment determine the maximum sound levels from construction activities.

The alternatives incorporate project features (IAMFs) to avoid or minimize potential effects from construction and operations. NV-IAMF#1: Noise and Vibration would require the contractor to prepare and submit to the Authority prior to construction a noise and vibration technical memorandum documenting how the FTA and FRA guidelines for minimizing construction noise and vibration impacts would be employed when work is conducted within 1,000 feet of sensitive

receptors. Typical construction practices in the FRA guidance manual (FRA 2012) for minimizing construction noise and vibration impacts include the following:

- Build noise barriers, such as temporary walls or piles on excavated material, between noisy activities and noise-sensitive resources.
- Route truck traffic away from residential streets where possible.
- Build walled enclosures around especially noisy activities or around clusters of noisy equipment.
- Combine noisy operations so they occur in the same period.
- Phase demolition, earthmoving, and ground-impacting operations so they do not occur in the same period.
- Avoid impact pile driving where possible in noise- and vibration-sensitive areas.

Application of the FRA and FTA guidelines would minimize temporary construction effects on sensitive receptors. However, there is still the potential for adverse effects from construction noise for sensitive receptors located close to construction activity.

Table 5-3 shows data on noise emissions of construction equipment. It includes average values of the L_{max} for various pieces of typical construction equipment at a distance of 50 feet. The data are from Table 10-1 of the FRA guidance manual.

Table 5-3 Construction Equipment Noise Emission Levels

Equipment	Typical Noise Level at 50 feet from Source (dBA)
Auger drill rig[1]	85
Backhoe	80

Vacuum excavator (vac-truck)[1]	85
Helicopter at 200 feet altitude[2]	84-89[2] (overflight) 89[2] (hovering)

Sources: FRA 2012; FHWA 2006;
dBA = A-weighted decibel
[1] Reference level from FHWA Roadway Construction Noise Model (FHWA 2006).
[2] SEL based on expected noise emissions from construction helicopters (Wilson Ihrig 2009).

Predicting construction noise requires a construction scenario of the equipment that would likely be used and average utilization factors. Utilization factors represent the percentage of time the equipment would be expected to be operating during each phase. Analysts used the typical noise levels for various pieces of equipment to calculate the L_{eq} at various distances from a construction site. Additional noise level data and utilization factor data were obtained from the FHWA *Roadway Construction Noise Model* (FHWA 2006).

Analysts identified five typical types of construction activities that would be used for project construction for analysis. Table 5-4 shows the results of the analysis. For each typical planned construction activity, including the PG&E network upgrades construction, the expected noisiest pieces of equipment are listed. For this level of detail, analysts assumed that all pieces of equipment would be located at the center of the construction site. The projection for the PG&E upgrades includes noise generated by helicopter overflights and hovering at the network tower installation location. The total 8-hour L_{eq} was calculated by incorporating the typical maximum sound levels of each piece of equipment and the utilization factor. For each construction activity type, the projections were adjusted to calculate the distance at which the L_{eq} would reach the criteria shown in Table 5-4.

The criteria are based on land use, with the most stringent category being for residential locations. For typical track construction scenarios, the residential nighttime 8-hour L_{eq} criterion of 70 dBA would potentially be exceeded up to 374 feet from the clear and grub construction activity, and as far away as 774 feet from the concrete pour aerial structure activity. These distances would be applicable to all four project alternatives because the same construction scenarios would apply to all of the alternatives. Concrete pour aerial structure activity would not apply to Alternative 4 between San Jose and Gilroy.

For the PG&E upgrade construction scenarios, the residential nighttime 8-hour L_{eq} criterion of 70 dBA would be exceeded up to 158 feet from the haul material construction activity and as far away as 522 feet from the conductor installation construction activity. These distances would be applicable to all four project alternatives because the same construction scenarios apply to all four alternatives. The Skyway Drive Variants A and B result in no measurable differences in noise impacts on sensitive receptors associated with Alternative 2.

Table 5-4 Construction Activity Noise Levels

Construction Activity	Equipment Type	Total 8-Hour Leq (dBA) at 50 feet	Distance to 70 dBA[1] Residential Nighttime Criterion (feet)	Distance to 80 dBA[1] Residential Daytime Criterion (feet)	Distance to 85 dBA[1] Commercial Criterion (feet)	Distance to 90 dBA[1] Industrial Criterion (feet)
Track Construction						
Clear and grub	Dump truck, water truck, rubber tired dozer, loader, crane	87	374	118	66	37

L_{eq} = equivalent sound level
dBA = A-weighted decibel
[1] Distances for this analysis assume that all pieces of equipment are located at the center of the construction site.

Table 5-5 shows key differences among the alternatives that would affect how construction noise affects the communities. Areas with embankments could include retaining structures, and embankment and at-grade could include vibratory compaction. The right-of-way blended areas might also require a greater amount of nighttime work to minimize service disruptions.

Table 5-5 Differences Among Alternatives

Subsection	Alt. 1	Alt. 2	Alt. 3	Alt. 4
San Joaquin Valley	Aerial/embankment			
Pacheco Pass	Mostly tunnel			
Morgan Hill and Gilroy	Aerial	Embankment/at grade	Far east aerial would avoid downtown Gilroy and Morgan Hill	At grade, right-of-way blended
Monterey Corridor	Aerial	Embankment	Aerial	At grade, right-of-way blended
San Jose Diridon Station Approach	Aerial/interchange touchdown at I-880	Aerial/interchange Touchdown at Scott	Same as Alt 2	At grade, right-of-way blended

I = Interstate

For the Morgan Hill and Gilroy Subsection, construction of the viaduct structure (Alternative 1 and 2) would have a larger criterion distance than the embankment and at-grade track options (Alternatives 2 and 4, respectively) because of height of the structure and the concrete pumps. For the Monterey Corridor Subsection and the San Jose Diridon Approach Subsection, the aerial viaduct (Alternatives 1 and 2) similarly would have a larger criterion distance than Alternatives 2 and 4. Nighttime construction could be required for Alternative 4 to minimize disruption of existing passenger rail services.

5.1.2.2 Operations Noise Impacts

This section describes the projected noise impacts related to HSR train operations, activities near the HSR stations, and conceptual operations at maintenance facility locations for the 2029 and 2040 conditions.[9]

As discussed in Section 4.1.3, the FRA noise impact criteria are based on a comparison of future projected noise levels to existing noise levels. Where the project alternatives would cause existing noise sources to change, such as by shifting an existing rail alignment, those changes become part of the projected noise levels.

Additionally, when a noise source in the RSA is known to be changing either with or without the project alternatives, that change in future noise is included in the future projections as well. The assumption for this project is that the Caltrain PCEP will happen regardless of the HSR project. Therefore, either with or without the project alternatives, the future noise levels in part of the RSA will change. To quantify the effect of the project alternatives, the future noise levels at all noise-sensitive receptors were calculated both with and without the project alternatives and compared to the existing levels.

This analysis evaluates the No Project Alternative and the project alternatives in 2029 and 2040. Under the 2029 and 2040 No Project conditions, changes in noise levels would be associated with the Caltrain PCEP and the increased operations of other adjacent passenger and freight

[9] A qualitative noise impact analysis of the Interim 2025 Plus Project condition (an initial operating section of HSR service between San Jose Diridon Station to the Central Valley prior to commencement of service on the entire Phase 1 system in 2029), was also evaluated. The Interim 2025 Plus Project condition would include significantly fewer daily HSR trains than the 2029 Plus Project condition, and as a result, associated operations noise impacts would be substantially less under the Interim 2025 Plus Project condition than the 2029 Plus Project condition. Therefore, this analysis does not further address the Interim 2025 Plus Project condition.

railroads. Because the Caltrain PCEP would upgrade the existing diesel locomotives with new, quieter EMU trains, which would reduce noise levels, it is anticipated that any noise impacts under the No Project conditions would be associated with increased operations of non-Caltrain passenger rail and freight rail service in the existing rail corridor. The 2029 and 2040 Plus Project condition evaluates changes in noise associated with implementation of the Caltrain PCEP and the HSR project. The 2029 and 2040 Plus Project cumulative conditions evaluates changes in noise levels associated with project operations, in addition to implementation of the Caltrain PCEP and increased operations of passenger and freight railroads in the corridor.

Table 5-6 shows the results of the 2029 No Project and 2029 Plus Project noise impact assessment. In all cases the noise impact is determined from the increase in noise over the existing condition. Alternative 1 would result in 47 severe impacts and 310 moderate impacts, Alternative 2 would result in 38 severe impacts and 599 moderate impacts,[10] Alternative 3 would result in 34 severe impacts and 227 moderate impacts, and Alternative 4 would result 190 severe impacts and 1,001 moderate impacts. Alternative 4 would have the most severe and moderate operations noise impacts, followed by Alternative 2, Alternative 1, and Alternative 3.

Noise impacts, before mitigation, associated with the DDV (which applies only to Alternative 4 in the San Jose Diridon Station Approach Subsection) and the TDV (which applies to all alternatives within the Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections) are shown in parentheses in Table 5-6. In some cases, receptors that would not have moderate or severe noise impacts with the preliminary design would have moderate or severe impacts with the DDV and TDV. In some cases, receptors that would have moderate noise impacts with the preliminary design would have severe impacts with the DDV and TDV. With the DDV and TDV, Alternative 1 would result in 51 severe impacts and 313 moderate impacts, Alternative 2 would result in 43 severe impacts and 601 moderate impacts,[11] Alternative 3 would result in 37 severe impacts and 233 moderate impacts, and Alternative 4 would result 197 severe impacts and 1,004 moderate impacts.

The difference in operations noise impacts among the four alternatives is predominately a result of the vertical and horizontal profile of each alternative. The greatest difference among the alternatives would occur in the Morgan Hill and Gilroy Subsection. Many Alternative 4 noise impacts would be from the HSR train horns in the Project Section. Alternative 2 would have a longer embankment profile than Alternatives 1 and 3, which are both predominately on aerial structures. Although the aerial structures of Alternatives 1 and 3 would be much higher in the air (which can sometimes lead to higher sound levels because of less ground attenuation), the design of the aerial structures includes a 3-foot-high parapet wall that functions as a short noise barrier. This parapet wall would reduce the noise levels from the propulsion and wheel-rail subsources under Alternatives 1 and 3, resulting in fewer noise impacts compared to Alternative 2. The horizontal alignment near Gilroy further differentiates the noise and vibration impacts among the four project alternatives. Alternatives 1 and 2 would extend through downtown Gilroy, while Alternative 3 would extend east of Gilroy through rural agricultural lands that are sparsely populated and have fewer sensitive receptors.

[10] The Skyway Drive Variants A and B under Alternative 2 would result in no measurable differences in noise impacts on sensitive receptors.

[11] The Skyway Drive Variants A and B under Alternative 2 would result in no measurable differences in noise impacts on sensitive receptors.

[1] FRA Land Use Categories are summarized in Table 4-3. Land Use Category 1 = areas where quiet is an essential element to the land use; Category 2 = Residential; Category 3 = Institutional use and passive-use parks.
[2] Impacts associated with the design variants are shown in parentheses. The DDV affects Alternative 4 within the San Jose Diridon Station Approach Subsection; the remaining noise impacts are associated with the TDV.

A cumulative noise impact assessment was also conducted for both the 2029 No Project and 2029 Plus Project conditions. In all cases the noise impact is determined from the increase in cumulative noise over the existing condition. The cumulative analysis assumes that the Caltrain PCEP will be implemented and that the increase in other passenger and freight operations in 2029 (shown in Table 4-9) would occur. Table 5-7 shows the 2029 No Project and Plus Project cumulative noise impact assessment results. The results indicate that under the 2029 No Project cumulative condition there would be 9 severe noise impacts and 841 moderate noise impacts caused by increases in other, non-HSR train operations. Under the 2029 Plus Project cumulative condition there would be 71 severe noise impacts and 1,620 moderate impacts under Alternative 1; 200 severe impacts and 1,426 moderate impacts under Alternative 2; 48 severe impacts and 1,306 moderate impacts under Alternative 3; and 475 severe noise impacts and 1,500 moderate impacts under Alternative 4. Future 2027 CNEL airport noise contours for San Jose International Airport (2010) have also been used to evaluate the cumulative condition.

Noise impacts associated with the DDV and TDV are shown in parentheses in Table 5-7. Under the 2029 Plus Project cumulative condition with the DDV and TDV, there would be 75 sensitive receptors that would experience severe impacts and 1,623 sensitive receptors that would experience moderate impacts under Alternative 1; 205 severe impacts and 1,427 moderate impacts under Alternative 2; 51 severe impacts and 1,312 moderate impacts under Alternative 3; and 501 severe impacts and 1,496 moderate impacts under Alternative 4.

[1] FRA Land Use Categories are summarized in Table 4-3. Land Use Category 1 = areas where quiet is an essential element to the land use; Category 2 = Residential; Category 3 = Institutional use and passive-use parks.
[2] Impacts associated with the design variants are shown in parentheses. The DDV affects Alternative 4 within the San Jose Diridon Station Approach Subsection; the remaining noise impacts are associated with the TDV.

Table 5-8 shows the results of the 2040 No Project and 2040 Plus Project condition noise impact assessment. In all cases the noise impact is determined from the increase in noise over the existing condition. Alternative 1 would result in 337 severe impacts and 1,200 moderate impacts; Alternative 2 would result in 755 severe impacts and 1,844 moderate impacts; Alternative 3 would result in 222 severe impacts and 834 moderate impacts; and Alternative 4 would result in 1,212 severe impacts and 1,666 moderate impacts. The results of the 2040 Plus Project noise impact assessment indicate more noise impacts than the 2029 Plus Project noise impact assessment results due to significantly more HSR train operations in 2040. Many Alternative 4 noise impacts would result from the HSR train horns in the Project Section. The existing noise from non-project elements was unchanged, such as the airports and local roads.

Noise impacts associated with the DDV and TDV are shown in parentheses in Table 5-8. Under the 2040 Plus Project condition with the DDV and TDV, there would be 347 sensitive receptors that would experience severe impacts and 1,195 sensitive receptors that would experience moderate impacts under Alternative 1; 766 severe impacts and 1,838 moderate impacts under Alternative 2; 233 severe impacts and 845 moderate impacts under Alternative 3; and 1,224 severe impacts and 1,658 moderate impacts under Alternative 4.

Analysts also conducted a cumulative noise impact assessment for both the 2040 No Project and 2040 Plus Project conditions. The cumulative analysis assumes that the Caltrain PCEP will be implemented and that the increase in other 2040 passenger and freight operations (shown in Table 4-10) would occur. Table 5-9 shows the 2040 No Project and 2040 Plus Project cumulative noise impact assessment results. Under the 2040 No Project cumulative condition there would be 291 severe noise impacts and 1,506 moderate noise impacts caused by increases in other, non-HSR train operations. Under the 2040 Plus Project cumulative condition there would be 879 severe noise impacts and 2,556 moderate impacts under Alternative 1, 1,237 severe impacts and 1,932 moderate impacts under Alternative 2, 647 severe impacts and 2,357 moderate impacts under Alternative 3, and 1,589 severe impacts and 1,933 moderate impacts under Alternative 4. The results of the cumulative noise impact assessment for the 2040 No Project and 2040 Plus Project conditions indicate that there would be substantially more noise impacts in 2040 compared to 2029 because of the increase in other non-HSR train operations. Future 2027 CNEL airport noise contours for San Jose International Airport (2010) have also been used to evaluate the cumulative condition.

Noise impacts associated with the DDV and TDV are shown in parentheses in Table 5-9. Under the 2040 Plus Project cumulative condition with the DDV and TDV, there would be 890 sensitive receptors that would experience severe impacts and 2,550 sensitive receptors that would experience moderate impacts under Alternative 1; 1,249 severe impacts and 1,925 moderate impacts under Alternative 2; 658 severe impacts and 2,361 moderate impacts under Alternative 3; and 1,601 severe impacts and 1,928 moderate impacts under Alternative 4.

[1] FRA Land Use Categories are summarized in Table 4-3. Land Use Category 1 = areas where quiet is an essential element to the land use; Category 2 = Residential; Category 3 = Institutional use and passive-use parks.
[2] Impacts associated with the design variants are shown in parentheses. The DDV affects Alternative 4 within the San Jose Diridon Station Approach Subsection; the remaining noise impacts are associated with the TDV.
Mod = Moderate
Sev = Severe

Implementation of the project alternatives would change the current practices regarding the sounding of train horns and crossing bells in the noise RSA. Alternatives 1, 2, and 3 would be grade separated and would not regularly sound warning horns between the San Jose and Gilroy HSR stations. However, one existing at-grade railway crossing at Bloomfield Avenue in Gilroy would be eliminated with Alternative 1, eliminating horn noise at that location. Alternative 2 would be predominately located on an embankment in or adjacent to the existing Caltrain/UPRR railway, which would necessitate the elimination of 33 existing at-grade crossings where trains currently sound warning horns. The elimination of at-grade crossings associated with Alternative 2 would produce a beneficial impact because of reduced noise exposure from horns and crossing bells. Existing trains would still sound horns at Caltrain stations with Alternative 2.

Alternative 4 would be located at grade at the same locations as the existing Caltrain and other passenger and freight operations. As a result, HSR trains under Alternative 4 would regularly sound warning horns at all at-grade crossings and Caltrain passenger stations.

Based on the current tunnel designs, it is anticipated that roughly half of the sound generated in the tunnel would pass out through the portal, and the other half would propagate into the interior. The effect would be a rapid rise in sound level as the train leaves the tunnel and portal, forewarned by a propagating wave ahead of the train. Depending on the shape of the portal, shape of the train nose, and blockage ratio, the rate of pressure rise may be substantial. The pressure wave front rate of rise is reduced by friction between the moving air column and tunnel wall, so that the pressure wave does not easily develop into a shock wave. This portal noise effect has been studied theoretically and experimentally and is well understood. Attenuation of the portal noise is achieved with long, flared portals and low blockage ratios. In-tunnel cross-passages and vents can reduce pressure magnitudes and rates of rise, though passage of these vents may generate additional propagating and steepening wave fronts. This tunnel and tunnel portal design features will be used to attenuate any additional noise associated with the train entering or exiting a tunnel.

Tables 5-10 through 5-13 show a detailed breakdown of the 2040 Plus Project noise impact assessment results for each subsection. The subsections are divided into smaller areas by cross streets or other features. In each location, ranges of distance to the nearest HSR track and maximum HSR speed are shown. The ranges shown represent a composite of many receptors and are meant to provide the upper and lower limits of these values for each geographic location. In locations with noise impacts, the data represent the range for those affected receptors. In locations without noise impacts, the data are representative of the receptor with the largest projected noise level increase (typically the receptor located closest to the alignment).

The detailed impact tables provide ranges of existing noise levels, predicted future noise levels, and predicted increase in noise levels. The range of the impact criteria are also given for moderate and severe impacts in these areas. The numbers of moderate and severe noise impacts in each location are provided. In each area, the specific land uses of the projected noise impacts are included. Most of the noise impacts would occur at single-family residences; several multifamily residential buildings would also be affected. Results with the DDV and TDV are shown in parentheses where they are different than the results without the DDV and TDV.

Table 5-10 Detailed 2040 Plus Project Noise Impacts—Alternative 1

Location	Land Use Category	Distance to Near HSR Track (feet)[1]	Maximum HSR Speed (mph)	Existing Noise Level (dBA)	Future Noise Level[2]		Noise Impact Criteria		Number of Impacts

Sta. = Station
[1] The ranges shown for the distances, speeds, and noise levels in this table are a composite of many receptors and are meant to provide the limits of these values for each geographic location. In locations with noise impacts, the data represent the range for those affected receptors. In locations without noise impacts, the data are representative of the receptor with the highest projected noise level increase (typically the receptor located closest to the alignment.)
[2] Noise levels for land use category 2 are based on L_{dn} and measured in dBA. Noise levels for land use categories 1 and 3 are based on L_{eq} and measured in dBA.
[3] Predicted future noise levels represent the total future predicted noise levels with the project alternatives.
[4] Increases in noise level represent the predicted increase in future noise levels with the project alternatives over the existing noise levels.
[5] Results associated with the TDV are shown in parentheses.
[6] Airborne noise was not assessed in this portion of the alignment where the alternative is in a tunnel.

[1] The ranges shown for the distances, speeds, and noise levels in this table are a composite of many receptors and are meant to provide the limits of these values for each geographic location. In locations with noise impacts, the data represent the range for those affected receptors. In locations without noise impacts, the data are representative of the receptor with the highest projected noise level increase (typically the receptor located closest to the alignment.)

[2] Noise levels for land use category 2 are based on L_{dn} and measured in dBA. Noise levels for land use categories 1 and 3 are based on L_{eq} and measured in dBA.

[3] Predicted future noise levels represent the total future predicted noise levels with the project alternatives.

[4] Increases in noise level represent the predicted increase in future noise levels with the project alternatives over the existing noise levels.

[5] Results associated with the DDV and TDV are shown in parentheses.

[6] Airborne noise was not assessed in this portion of the alignment where the alternative is in a tunnel.

Annoyance from Onset of HSR Passbys

Operations of the project would result in a sudden increase in noise for receivers along the alignment because of the rapid approach of an HSR train and a quick onset rate. Onset rate is the average rate of change of increasing sound pressure level measured in decibels per second (dB/sec) during a single noise event. The rapid approach of an HSR train is accompanied by a sudden increase in noise for a receiver near the tracks. As described in Section 4.1.3.2, Operations, startle effects are likely to occur in humans as onset rates approach 30 dB/sec when there is no advance warning of train approach.

Trains for all project alternatives would reach maximum speeds of 220 mph in certain portions of the alignments with dedicated track. As illustrated on Figure 4-5, the onset rate of 30 dB/second would be experienced by receptors within 46 feet of the train when the train is operating at 220 mph and within 23 feet when the train is operating at 110 mph. For speeds between 110 mph and 220 mph, the onset rate of 30 dB/second would be experienced at distances between 23 and 46 feet from the train. For speeds less than 110 mph, the onset rate of 30 dB/second would be experienced at distances of less than 23 feet from the train.

The project's dedicated right-of-way would be a minimum of 85 feet wide. In addition, the dedicated segments are usually on viaduct or embankments instead of at-grade, which introduces additional vertical distance separation from sensitive receptors. As the distance for the startle effect for humans is 46 feet, it is expected that the distance in which startle effects would occur would be within the dedicated right-of-way. This would apply to Alternative 1 south of I-880, Alternatives 2 and 3 south of Scott Boulevard, and Alternative 4 south of Gilroy.

Under Alternative 1, blended operations would occur between Scott Boulevard and I-880 but the right-of-way is sufficiently wide that there are no noise-sensitive receptors within 23 feet of the planned track alignments.

Under Alternative 4, blended operations would occur between Scott Boulevard in Santa Clara and San Jose and Gilroy, with speeds up to 110 mph; noise-sensitive receptors located within 23 feet of the alignment would experience an onset rate of 30 dB/second. Between Scott Boulevard and the San Jose Diridon Station, there is extensive daily train traffic along the Caltrain Corridor, including Caltrain (92 daily trains), ACE (8 daily trains), Capitol Corridor (14 daily trains), Amtrak (2 daily trains), and freight (9 daily trains). Between the San Jose Diridon Station and Tamien Station, a moderate amount of daily train traffic operates along the Caltrain Corridor including Caltrain (40 daily trains), ACE (8 daily trains), Amtrak (2 daily trains), and freight (4 daily trains). Between Tamien and Gilroy, there is limited existing daily train traffic along the Caltrain and UPRR corridors including Caltrain (6 daily trains), Amtrak (2 daily trains), and freight (4 daily trains). In these areas, trains operate up to 79 mph at present.

Passengers may be on Caltrain or HSR platforms closer than 23 feet from the tracks. However, there would be advance warning of trains approaching with announcements, horns, bells, and signage, so substantial, ongoing startle effects would not occur there with train passage. The same would be true at the at-grade crossings for vehicles, bicyclists, and pedestrians under Alternative 4.

Analysts reviewed the Alternative 4 alignment between Scott Boulevard in Santa Clara and Gilroy and found that in most areas (outside of stations and at-grade crossings) there would be more than 23 feet from the outermost track to sensitive noise receptors, and no startle effects would occur. Analysts identified one noise-sensitive receptor (a residence) within 23 feet of the

Alternative 4 tracks (receptors in properties not immediately adjacent to the railroad right-of-way would not be affected):[12]

- Morgan Hill and Gilroy Subsection
  - In Morgan Hill, one mobile home east of Wright Avenue west of the right-of-way south of Butterfield Boulevard, is within 23 feet of the proposed southbound track.

Operations of all four project alternatives would result in wayside noise near the tunnel portals in Pacheco Pass, which could startle nearby wayside receptors. As described in detail in Volume 2, Appendix 3.4-A, because the closest receptors to the tunnel portals are more than 1,000 feet away, wayside noise near the tunnel portals is not expected to cause an adverse effect on sensitive receptors.

Station Noise

The project includes the construction of two HSR stations – one passenger station would be located in San Jose adjacent to the existing San Jose Diridon Station and the other would be located in Gilroy. The San Jose Diridon Station would be the same for all four alternatives. Two station location options have been identified in Gilroy—a Downtown Gilroy Station located adjacent to the existing Gilroy Caltrain Station would be used for Alternatives 1, 2, and 4, while an East Gilroy Station would be constructed in agricultural lands east of Gilroy for Alternative 3.

The method used to assess noise impact from HSR stations is summarized in Section 4.1.5.2, Operations Noise. The dominant noise source at receptors near the HSR stations would be assumed to be HSR train movements. This analysis also assessed additional noise from station parking facilities. Preliminary layouts of the parking facilities at the HSR stations were used to identify the location and total number of parking spaces at each station location options—San Jose Diridon Station, Downtown Gilroy Station, and East Gilroy Station.

The San Jose Diridon Station would be the same for Alternatives 1-3, with a variation for Alternative 4, and would remove and relocate approximately 226 parking spaces. The Downtown Gilroy Station would have four parking areas with approximately 1,710 spaces, and the East Gilroy Station would have two parking areas with approximately 1,520 spaces. The analysis assumed that on a typical day during the three peak morning hours and three peak afternoon hours all the parking spaces would be filled once and then vacated once. During the non-peak mid-day and evening hours, the analysis assumed that a percentage of the parking spaces corresponding to the ridership peaking factors (Authority 2008) would be filled and then vacated each hour.

A noise assessment following Section 4.4 of the FTA guidance manual (FTA 2018) was conducted using these inputs and the method in Section 4.1.5.2, Operations Noise, to calculate the total noise contribution from the parking facilities at the noise-sensitive receptors near the HSR stations. Near the San Jose Diridon Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 29 dBA. Near the Downtown Gilroy Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 40 dBA. Near the East Gilroy Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 28 dBA. The results of the station noise assessment indicate that the additional noise from parking facilities would be substantially lower than the projected L_{dn} from project operations. At all nearby receptors, the L_{dn} contribution from the parking facilities would be at least 18 dB less than project operations.

Maintenance Facility Noise

One MOWF would be located near Gilroy under each project alternative. There are two potential location options for the MOWF—a South Gilroy MOWF (located south of the Downtown Gilroy Station under Alternatives 1 and 2) and an East Gilroy MOWF (located south of the East Gilroy

[12] If residences are proposed for acquisition, they are not included in the profile of potentially affected areas, as residents would not be present during operations.

Station under Alternative 3). At both locations, the mainline HSR tracks would be directly adjacent to the MOWF and the HSR speeds would be approximately 200 mph. Therefore, the noise from project operations would dominate noise from occasional HSR train movements into and out of the MOWF.

Analysts used the methods to assess noise impacts from the proposed MOWFs summarized in Section 4.1.5.2, Operations Noise. Preliminary layouts of the two MOWFs were used to identify the approximate center of noise-producing activities at the facilities. A noise assessment following Section 4.4 of the FTA guidance manual was used to predict noise exposure from the MOWFs. The project operations schedule of train movements into and out of the MOWFs identified 24 planned HSR train movements during the daytime and 12 movements during the nighttime. The L_{dn} contribution from these MOWF train movements was then calculated at all nearby noise-sensitive receptors.

The closest identified receptor (single-family residence on Bolsa Road) to the South Gilroy MOWF is more than 1,500 feet away. The L_{dn} contribution from the South Gilroy MOWF at that nearest receptor would be 40 dBA, more than 20 dB less than the project operations contribution at that receptor. The nearest receptors (residences on Pacheco Pass Highway in the rural residential Old Gilroy neighborhood) to the East Gilroy MOWF would be approximately 800 feet away. In this neighborhood, the highest L_{dn} contribution from the East Gilroy MOWF would be 47 dBA, more than 20 dB less than the operations contribution at that receptor. The nearest receptors to the Alternative 4 South Gilroy MOWF are approximately 900 feet away. In this neighborhood, the highest L_{dn} contribution from the MOWF would be 45 dBA, more than 18 dB less than the operations contribution at that receptor. As a result, the additional noise from all of the MOWFs would not contribute to noise impacts of nearby sensitive receptors.

Vehicle Traffic Noise

In addition to noise from project train operations, noise from changes in vehicle traffic volume from the project was considered for 2029 and 2040 No Project and Plus Project conditions. The project would require the relocation of some local roads; however, traffic on local roads provides only a minor contribution to overall noise levels in the project extent. A number of existing at-grade crossings would be eliminated with Alternative 2 but these are not expected to result in increases in traffic volume. Monterey Road is the only major roadway that would be substantially reconfigured by the project, with the reduction of travel lanes from six to four lanes between approximately the Capitol Expressway and Blossom Hill Road.

Noise from changes in traffic volume due to the project was assessed following the method summarized in Section 4.1.5.2. The traffic noise analysis focused on roadway segments near the HSR stations, the MOWFs, and along Monterey Road where there would be permanent lane reductions. Daily traffic volumes for these select roadway segments were used to calculate traffic growth factors to assess the potential change in noise levels for each project alternative for 2029 and 2040.

Table 5-14 identifies the roadway segments assessed for Alternative 1 in 2029. It includes the existing total average daily traffic (ADT) volumes for each roadway segment, the 2029 No Project ADT, and the 2029 Plus Project ADT for Alternative 1. The potential noise increases over existing noise conditions and over the No Project Alternative are calculated. This assessment identifies that four roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. In all cases the noise impact is determined from the increase in noise over the existing condition. For context, in comparison with the No Project Alternative, two roadway segments have the potential for an increase of 3 dB. All other segments show increases of 2 dB or less over the No Project case.

Along Monterey Road, two segments have the potential for increases of 3 dB or greater compared to existing noise conditions. However, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. All comparisons to the No Project Alternative are for informational purposes only, and not a determinant of impact. None of the roadway segments near the Downtown Gilroy Station would have a noise level increase greater

than 1 dB compared to existing noise conditions or the No Project Alternative. The largest increase in noise level for the east Gilroy roadway segments is 1 dB compared to existing noise conditions, with no increase compared to the No Project Alternative. Near the South Gilroy MOWF, one segment has the potential for a 3 dB increase compared to existing noise conditions and the No Project Alternative.

ADT = average daily traffic
dBA = A-weighted decibel
MOWF = maintenance of way facility
[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Table 5-15 shows the roadway segments assessed for Alternative 2 in 2029. Four roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. In all cases the noise impact is determined from the increase in noise over the existing condition. For context, in comparison with the No Project Alternative, two roadway segments have the potential for an increase of 3 dB. All other segments show increases of 2 dB or less compared to No Project.

Along Monterey Road, two segments have the potential for increases of 3 dB or greater compared to existing noise conditions. However, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. None of the roadway segments near

the Downtown Gilroy Station would have a noise level increase greater than 1 dB compared to existing noise conditions or the No Project Alternative. The largest increase in noise level for the east Gilroy roadway segments is 1 dB compared to existing noise conditions, with no increase compared to the No Project Alternative. Near the South Gilroy MOWF, one segment has the potential for a 3 dB increase compared to existing noise conditions and the No Project Alternative.

[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Table 5-16 shows the roadway segments assessed for Alternative 3 in 2029. Four roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. Compared to the No Project Alternative, two roadway segments have the potential for an increase of 3 dB. All other segments show increases of 2 dB or less. Along Monterey Road, two segments have the potential for increases of 3 dB or greater compared to existing noise conditions. In all cases the noise impact is determined from the increase in noise over the existing condition. For context, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. None of the roadway segments near the Downtown Gilroy Station would have a noise level increase greater than 1 dB compared to existing noise conditions. No increase is anticipated compared to the No Project

Alternative. One roadway segment near east Gilroy has the potential for an increase of 2 dB compared to existing noise conditions. The largest increase compared to the No Project Alternative is 1 dB. Near the East Gilroy MOWF, no increase is anticipated compared to either the existing or the No Project Alternative.

[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.
ADT = average daily traffic
dBA = A-weighted decibel
MOWF = maintenance of way facility

Table 5-17 shows the roadway segments assessed for Alternative 4 in 2029. Three roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. Compared to the No Project Alternative, zero roadway segments have the potential for an increase greater than 1 dB. Along Monterey Road, three segments have the potential for increases of 3 dB or greater compared to existing noise conditions. In all cases the noise impact is determined from the increase in noise over the existing condition. For context, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. None of the roadway segments near the Downtown Gilroy Station would have a noise level increase greater than 2 dB compared to existing noise conditions or the No Project Alternative. The largest increase in noise level for the east Gilroy

roadway segments is 1 dB compared to existing noise conditions, with no increase compared to the No Project Alternative. Near the South Gilroy MOWF, the largest increase in noise level compared to existing noise conditions or the No Project Alternative is 1 dB.

5	Monterey Road between 10th Street and Travel Park Circle	14,956	16,222	17,361	1	0

ADT = average daily traffic
dBA = A-weighted decibel
MOWF = maintenance of way facility
[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Overall, there are relatively few roadway segments where the noise increases associated with the project alternatives in 2029 are anticipated to be greater than or equal to 3 dB. Most of those segments where increases greater than or equal to 3 dB are projected are near San Jose Diridon Station and some along the Monterey Road segment. The results of the traffic noise analysis for 2029 are similar for all project alternatives, and differ only near the MOWF near Gilroy.

Table 5-18 shows the roadway segments assessed for Alternative 1 in 2040. It includes the existing ADT volumes for each roadway segment, the 2040 No Project ADT, and the 2040 Plus Project ADT for Alternative 1. This assessment indicates that for Alternative 1 in 2040, five roadway segments near San Jose Diridon Station would have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. Compared to the

2040 No Project Alternative, one roadway segment has the potential for an increase of 3 dB. All other segments show increases of 1 dB or less. Along Monterey Road, six segments have the potential for increases of 3 dB or greater compared to existing noise conditions. However, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. None of the roadway segments near the Downtown Gilroy Station would have a noise level increase greater than 2 dB compared to existing noise conditions, or greater than 1 dB compared to the No Project Alternative. The largest increase in noise level for the east Gilroy roadway segments would be 2 dB compared to existing noise conditions, with no increase compared to the No Project Alternative. Near the South Gilroy MOWF one segment has the potential for a 3 dB increase compared to existing noise conditions and the No Project Alternative.

[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Table 5-19 shows the roadway segments assessed for Alternative 2 in 2040. Five roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. Compared to the 2040 No Project Alternative, one roadway segment has the potential for an increase of 3 dB. All other segments show increases of 1 dB or less. Along Monterey Road, six segments have the potential for increases of 3 dB or greater compared to existing noise conditions. However, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. None of the roadway segments near the Downtown Gilroy Station would have a noise level increase greater than 2 dB compared to existing noise conditions, or greater than 1 dB compared to the No Project Alternative. The largest increase in noise level for the east Gilroy roadway segments is 2 dB compared to existing noise conditions, with no increase compared to the No Project Alternative. Near the South Gilroy MOWF, one segment has the potential for a 3 dB increase compared to existing noise conditions and the No Project Alternative.

[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Table 5-20 shows the roadway segments assessed for Alternative 3 in 2040. Five roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. Compared to the 2040 No Project Alternative, one roadway segment has the potential for an increase of 3 dB. All other segments show increases of 1 dB or less. Along Monterey Road, five segments have the potential for increases of 3 dB or greater compared to existing noise conditions. However, none of the segments would have an increase greater than 1 dB compared to the No Project Alternative. None of the roadway segments near the Downtown Gilroy Station would have a noise level increase greater than 2 dB compared to existing noise conditions or greater than 1 dB compared to the No Project Alternative. One roadway segment near east Gilroy as the potential for an increase of 3 dB compared to existing noise conditions and an increase of 1 dB compared to the No Project Alternative. Near the East Gilroy MOWF, the largest increase compared to existing noise conditions is 2 dB and 1 dB compared to the No Project Alternative.

ADT = average daily traffic
dBA = A-weighted decibel
MOWF = maintenance of way facility
[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Table 5-21 shows the roadway segments assessed for Alternative 4 in 2040. Four roadway segments near San Jose Diridon Station have the potential for noise level increases greater than or equal to 3 dB compared to existing noise conditions. Compared to the 2040 No Project Alternative, the largest increase is 2 dB, and all other segments show increases of 1 dB or less. Along Monterey Road, six segments have the potential for increases of 3 dB or greater compared to existing noise conditions. However, none of the segments would have an increase greater than 2 dB compared to the No Project Alternative. One roadway segment near the Downtown Gilroy Station would have a noise level increase greater than or equal to 3 dB compared to existing noise conditions, and compared to the No Project Alternative none would have increases greater than 2 dB. The largest increase in noise level for the east Gilroy roadway segments is 1 dB compared to existing noise conditions, with no increase compared to the No Project Alternative. Near the South Gilroy MOWF, one segment has the potential for an increase greater than 3 dB compared to existing noise conditions and the No Project Alternative.

(Parentheses) indicate negative values
ADT = average daily traffic
dBA = A-weighted decibel
MOWF = maintenance of way facility
[1] The noise increase over No Project data are presented only for reference purposes. The noise increase over existing is what determines impact.
[2] Monterey Road Roadway Segment number 6, Monterey Road between Chynoweth Avenue and Bernal Road, is in both the Monterey Corridor Subsection and the Morgan Hill and Gilroy Subsection.

Overall, there are relatively few roadway segments where the increases in traffic associated with the project alternatives under the 2040 Plus Project Alternative are anticipated to be greater than or equal to 3 dB. Most of the segments where increases greater than or equal to 3 dB are projected are near San Jose Diridon Station and some along the Monterey Road segment. The results of the traffic noise analysis for 2040 are similar for all project alternatives, and differ only near the MOWF near Gilroy.

The traffic noise predictions have been made by comparing the existing traffic volumes to 2040 Plus Project volumes and by comparing the 2040 No Project volumes to the 2040 Plus Project volumes. The traffic volume predictions include growth factors unrelated to the project alternatives. In all cases the noise impact is determined from the increase in noise over the existing condition. As would be expected, the analysis shows greater potential increases in traffic noise compared to the existing noise conditions than when compared to the No Project Alternative.

Noise Effects on Livestock Animals

The project would extend through rural, agricultural, and open space lands in southern Santa Clara, San Benito, and Merced Counties. Livestock (cattle) are present in rangelands along the project alignments, particularly in the Pacheco Pass Subsection. Additionally, dairy is an important agricultural product in Merced County and confined animal agricultural operations are prevalent in the San Joaquin Valley.

Operations of the project would stress livestock animals by subjecting them to increased noise and vibration levels within 30 feet of the HSR right-of-way. The FRA guidance manual (FRA 2012) establishes an SEL of 100 dBA from a single train passby as the criteria for potential noise impacts on livestock. The criteria for potential effects are shown in Table 4-4. Analysts conducted a noise screening assessment to determine typical and maximum distances from the HSR tracks at which the limits may be exceeded. HSR passby SELs were calculated for various track types typical in the project: at-grade track, track on 10-foot-high embankment, and track on 50-foot-high viaduct. The projections were calculated for a HSR train traveling at a typical speed of 150 mph and at the maximum speed in the Project Section of 220 mph. For reference, a projection was also calculated for a HSR train sounding a warning horn. To provide conservative estimates, no shielding from intervening structures was assumed.

Table 5-22 shows the results of the screening assessment. For HSR track at grade and on embankment, the screening distances for potential effects on animals would be 15 feet from the track centerline for trains traveling at 110 mph, 25 feet from the track centerline for trains traveling at 150 mph, and 70 feet for trains traveling at 220 mph. At locations where the project would be on a 50-foot-high viaduct, the passby SEL of 100 dBA would not be surpassed beyond the edge of the aerial structure, approximately 15 feet from the track centerline. At locations where the HSR train would sound warning horns, the screening distance would be approximately 285 feet from the track centerline. For reference, screening distances have also been calculated and added to Table 5-22 for a Caltrain train and a freight train passby sounding warning horns. The screening distances are 62 feet and 290 feet, respectively.

According to the screening distance information provided in Table 5-19, livestock might be within the screening distance for an at-grade or 10-foot-high embankment HSR (i.e., within 70 feet of either side of the track centerline [for a total width of 140 feet]). Because fences control access to the right-of-way and the right-of-way would be a minimum of 85 feet wide, livestock would have to be within approximately 30 feet of the edge of the HSR right-of-way to experience noise effects above the recommended threshold. Where domestic animal operations are adjacent to the HSR right-of-way, adverse effects would occur within 30 feet of the HSR right-of-way because of passbys or within 285 feet of horn-sounding locations. These impacts will be temporary and of short duration.

As described in Appendix 3.12-E, High-Speed Rail Impacts on Confined Animal Agriculture Facilities, several confined animal agriculture facilities along the HSR alignment would be located within 100 feet of the centerline of the project alignment in the San Joaquin Valley subsection, and livestock animals within 30 feet of the right-of-way fence could be affected by train passbys. The figures in Appendix 3.12-E, show confined animal agriculture facilities that would be affected by the alternatives. Livestock may become habituated to train noise over time.

Alternatives 1, 2, and 3 would be grade separated on dedicated tracks and thus no horn sounding would be necessary at any at-grade crossings, and since HSR would operate on tracks that are physically separate from Caltrain, HSR trains would not sound horns at Caltrain stations. For these reasons no horn-sounding effects on livestock would occur. With Alternative 4, HSR would sound horns at at-grade crossings and Caltrain stations between San Jose and Gilroy. In urban areas of San Jose, Morgan Hill, and Gilroy and the developed area of San Martin and adjacent to the Caltrain stations, there is limited to no livestock areas. Thus, potential horn-sounding effects on livestock with Alternative 4 are limited to the rural area between San Jose and Morgan Hill (e.g., Coyote Valley) and the semi-rural area between San Martin and Gilroy. In these two areas, livestock would be sporadically within the screening distance for an HSR train sounding the warning horn at an at-grade crossing (i.e., within 285 feet of either side of the track centerlines) similar to how existing livestock is within the screening distances for existing Caltrain and freight sounding warning horn noise at at-grade crossings. Horn sounding in these areas would increase in frequency, but horn intensity would not increase over current levels.

At locations adjacent to existing rail right-of-way or busy highways where existing noise is already high, there would be no effects because livestock would be expected to be habituated to high noise levels.

Table 5-22 Screening Distances for Effects on Livestock

HSR Configuration	Speed (mph)	SEL[1] (dBA)	Distance from HSR Centerline (feet)
HSR on at-grade track	110	100	15
	150	100	25
	220	100	70
HSR on 10-foot-high embankment	150	100	25
	220	100	70
HSR on 50-foot high viaduct[2]	150	88	15
	220	94	15
HSR on at-grade track, sounding warning horn	110	100	285
Caltrain on at-grade track, sounding warning horn	79	100	62
Freight train on at-grade track, sounding warning horn	60	100	290

mph = miles per hour
SEL = sound exposure level
dBA = A-weighted decibel
[1] The SEL represents a receptor's cumulative noise exposure from an event normalized to a 1-second interval. This noise descriptor is used to assess effects on livestock.
[2] The aerial structure projections assume a parapet barrier on the edge of the aerial structure assumed to be 3 feet above the top-of-rail height. The distance from the track centerline where the SEL = 100 dBA is less than 15 feet.

Traction Power Facility Noise

Analysts identified potentially affected noise-sensitive receivers near traction power facilities using the screening distance of 250 feet for receivers with an unobstructed view to the facilities and 125 feet for those with intervening buildings. FTA reference levels were used to calculate the total project noise level at the receivers identified within the screening distance. For Alternative 4, within the Diridon Station Approach subsection, the HSR TPF would be co-located with the Caltrain facility (PS2 – Option 2), which was previously analyzed for the PCEP (Wilson Ihrig 2014), for which no noise sensitive receptors were identified within the screening distance.

Train operations noise levels were also calculated using the methods described in Section 4.1.5.2 to assess the total project noise levels considering ambient noise at the receivers and accounting for both changes from project operations and the new substation/facility noise source. The noise levels from ancillary facilities were estimated. The highest noise levels from ancillary facilities would be 63 L_{dn} dBA at 110 feet, but no TPF would generate noise impact due to the substation facility alone. Furthermore, in combination with the HSR train operations, the substation noise would not affect any new receptors not separately affected by the train operation impacts shown previously in Table 5-23. TPF combined with HSR train operations would generate noise impacts at several areas (7 receptors with Alternative 1, 1 receptor for Alternative 2, 9 receptors with Alternative 3, and 33 receptors for Alternative 4). Furthermore, this analysis is conservative because distances were based on the closest outer footprint of facility, and the specific distance to noise sources would be greater in many cases.

L_{dn} = day-night sound level, dBA
dBA = A-weighted decibel
TPF = traction power facility
PS = paralleling station
MFR = multifamily residence
N: Building not affected by TPF for this alternative
N/A = not applicable
SFR = single-family residence
SWS = switching station
TPSS = traction power supply station
SR = State Route
[1] Facilities not listed have no noise sensitive receivers within 250 feet of the facility.
[2] FRA land use categories are summarized in Table 3.4-5. Land Use Category 1 = areas where quiet is an essential element to the land use; Category 2 = Residential; Category 3 = Institutional use and passive-use parks.
Take: property would be acquired by the Authority; buildings not counted
* Take only affects Alternatives 1, 2, and 4.

5.2 Vibration

5.2.1 Existing Vibration Environment

This section summarizes the locations of existing vibration measurement sites and the results of vibration measurement. This section also describes the vibration-sensitive land uses and sources of existing vibration in the RSA.

5.2.1.1 Vibration Measurement Results and Discussion

Measurements of the existing vibration levels were conducted at 14 sites in the RSA. The locations of the vibration measurement sites are illustrated on Figures 5-1 through 5-5, and photographs of these sites are provided in Appendix A.

The existing vibration measurement results are shown in Table 5-24. At each site, ground-borne vibration levels were recorded at multiple distances, and the range of distances from the track centerline from where the vibration levels were measured are shown in Table 5-24. The results include the range of maximum overall ground-borne vibration levels for each type of train passby based on the distance from the track. The range in measured vibration levels corresponds directly to the accelerometer or geophone distance from the track. Higher vibration levels occur closer to the existing tracks and the vibration levels decrease with distance from the track.

The FRA notes that typical outdoor sources of perceptible ground-borne vibration are construction equipment, steel-wheeled trains, and traffic on rough roads. If the roadway is smooth, the vibration from traffic is rarely perceptible (FRA 2012). For most of the RSA, the dominant existing vibration sources are train traffic. In subsections where the vibration RSA diverges from existing railroad right-of-way, there are no significant sources of existing vibration. Traffic on roadways can cause some vibration, but because of the rubber tires on the vehicles, those vibration levels are typically low and isolated to locations close to roadways; vibration from traffic is only mentioned if the levels are comparable to 72 VdB. The vibration-sensitive land uses in the RSA are generally located where the vibration RSA is adjacent to existing rail rights-of-way and therefore, where existing ambient vibration measurements were conducted.

VdB = vibration decibels

Figure 5-26 illustrates results of the existing vibration measurements. The overall ground-borne vibration velocity levels at each site at each measurement distance from the tracks are included. The various symbols in the figure identify the site and each type of train passby. For reference, the FRA residential vibration criterion of 72 VdB is also included, showing the range of distances at which existing train vibration currently exceeds the criterion. The measurements show that the vibration levels decrease with distance, which varies at each site as a function of distance from the track, the train type, and train speed. At most sites, the overall vibration levels exceeded the FRA residential criterion at locations less than 50 feet from the track and at some sites up to approximately 100 feet from the track, which is less than would typically be expected.

As discussed in Section 4.2.4, Methods for Establishing Existing Vibration Levels, vibration propagation measurements were conducted at 10 locations in the RSA to assist in the prediction of ground-borne vibration levels from project operations. The vibration propagation measurements shown in Table 5-25 are site-specific tests that quantify the efficiency of vibration propagation through the soil at specific locations. The results are used to conduct a detailed vibration analysis and predict future ground-borne vibration levels from project operations.

Surface vibration propagation tests were conducted at nine locations in the RSA. One borehole vibration propagation test was also conducted in the RSA during previous work in 2010. The LSR data from each propagation measurement site are plotted in Appendix C, which also provides LSR coefficients for each site.

[1] At site VP19, vibration propagation was measured at multiple borehole depths.
[2] No vibration propagation measurements were conducted in the Pacheco Pass Subsection because no sensitive receptors are near the project.

San Jose Diridon Station Approach Subsection

In San Jose, the vibration RSA follows the Caltrain right-of-way through moderately dense urban areas with mixed land use. North of San Jose Diridon Station, the land use on the east side of the existing rail alignment is primarily industrial, while the western side is mainly residential. The closest residence is approximately 50 feet from the existing railway line. Bellarmine College Preparatory School campus is on the western side of the vibration RSA. At San Jose Diridon Station, there are multifamily buildings along the entire west side of San Jose Diridon Station facing the existing tracks and platforms. Templo La Hermosa church is on the eastern side of the station, beyond the parking lots approximately 550 feet from the station.

South of San Jose Diridon Station, the vibration RSA follows I-280 and SR 87. Land uses include residential neighborhoods and some commercial/industrial areas. The San Jose Fire Department Bureau of Field Operations campus is located just south of San Jose Diridon Station on the east side of the RSA. Gardner Elementary School is located approximately 275 feet south of I-280 on the south side of the RSA.

Existing vibration in this portion of the RSA is dominated by a number of daily rail operations that share the alignment (Table 4-8). This alignment is a heavily used rail corridor with 92 daily weekday Caltrain passenger trains currently operating between San Francisco and San Jose Diridon Station. Forty daily Caltrain trains operate through to Tamien Station. Approximately two to nine freight trains run along the route per day. Fourteen Capital Corridor and eight ACE trains run along the alignment daily between De La Cruz Boulevard and San Jose Diridon Station. ACE trains continue to travel south to Tamien Station to access the layover facility. Amtrak Coast Starlight trains pass through the section twice daily. Santa Clara VTA light rail trains run along the center of SR 87.

Vibration from Caltrain trains was measured at three sites north of San Jose Diridon Station. Overall ground-borne vibration levels from Caltrain measured at the closest positions ranged from 79 VdB (at 50 feet) to 77 VdB (at 80 feet) from the tracks. The vibration levels from Amtrak trains measured at V33 were similar to Caltrain trains. Vibration levels from freight train operations measured at V33 ranged from 73 VdB (at 100 feet) to 64 VdB (at 270 feet).

Vibration from Caltrain trains was measured at three sites south of San Jose Diridon Station. Overall vibration levels from Caltrain at the closest positions ranged from 83 VdB (at 40 feet) to 68 VdB (at 105 feet). Vibration levels from ACE trains at V36 were lower than Caltrain trains.

Monterey Corridor Subsection

South of West Alma Avenue, the vibration RSA extends along SR 87 until south of Almaden Expressway where it turns east toward Monterey Road following the UPRR right-of-way. Land uses along the Monterey Corridor Subsection include primarily single-family residential neighborhoods and some commercial/industrial areas. Toward the southern end of the subsection, land uses include scattered single-family homes and farms.

The closest residence is approximately 30 feet from the existing railway line, near Skyway Drive, where backyards of single-family homes abut the right-of-way. An Elk's Lodge on West Alma Avenue is approximately 180 feet from SR 87 on the west side of the RSA. A recording studio is on the east side of the RSA, although it is approximately 350 feet from the existing railway and behind some intervening commercial buildings. The School of the Blues music school is located

on Monterey Road, approximately 190 feet from the existing railway line. Other institutional land uses include Edenvale Branch Library and four places of worship.

Sources of existing vibration include traffic on SR 87 and Monterey Road, as well as the existing rail traffic along UPRR. South of Tamien station the daily rail traffic consists of six Caltrain passenger trains, two Amtrak trains, and approximately four freight trains per day. VTA light rail also run along the center of SR 87.

Vibration from Caltrain trains was measured at site V38. Overall vibration levels from Caltrain ranged from 73 VdB (at 67 feet) to 54 VdB (at 217) feet from the tracks. Vibration from Caltrain trains was also measured at site V39. Overall vibration levels ranged from 70 VdB (at 82 feet) to 61 VdB (at 232) feet from the tracks.

Morgan Hill and Gilroy Subsection

Along Monterey Road through Downtown Gilroy

The vibration RSA extends along the single UPRR track from Bernal Way into downtown Gilroy. It continues past the existing Gilroy Caltrain Station, along UPRR south of downtown, and then turns east toward the Pacheco Pass Highway near Bloomfield Avenue. Land uses include farms with scattered single-family homes, and residential neighborhoods and commercial areas in Morgan Hill and San Martin. The closest residences to the existing railway line are a row of single-family homes approximately 40 feet away, where backyards abut the right-of-way, between Bernal Way and Metcalf Road. Three hotels are within 200 feet of the existing railway line. The closest school is approximately 145 feet from the existing railway line. The closest place of worship is located approximately 150 feet from the existing railway line. In downtown Morgan Hill, the Morgan Hill Community Center outdoor amphitheater is approximately 500 feet from the existing railway line and the South Valley Civic Theatre and Community Playhouse is more than 600 feet from the railway line.

In the downtown area, land uses include a mix of residential neighborhoods and commercial/industrial areas. South of downtown, land uses include farms with scattered single-family homes. The closest residential building to the existing railway line is approximately 50 feet from UPRR track on Monterey Road and Lewis Street. The closest school is Gilroy Preparatory School, which is approximately 145 feet from the existing railway line. Pintello Comedy Theater is approximately 365 feet from the existing railway line and the District Theater Live Music Venue is 50 feet from the railway line.

Sources of existing vibration include existing rail traffic along UPRR (six Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day). Caltrain trains stop at the existing Gilroy station, which is where Caltrain service terminates. Amtrak and freight trains continue to operate south of Gilroy. Low level vibration occurs from traffic on Monterey Road.

Vibrations from Caltrain trains were measured at five sites from Morgan Hill to Gilroy. Overall ground-borne vibration levels from Caltrain measured at the closest positions ranged from 78 VdB (at 44 feet) to 71 VdB (at 50 feet) from the tracks. Levels at the farthest measured distances ranged from 67 VdB (at 100 feet) to 56 VdB (at 150 feet).

Adjacent to US 101 through Morgan Hill

Land uses include farms with scattered single-family homes, and residential neighborhoods and commercial areas in Morgan Hill near El Camino Real/US 101. For most of this RSA, there are no existing rail vibration sources and the existing low-level vibration environment is primarily traffic on US 101 and local streets. At connection points on both ends, some receptors are exposed to the existing rail traffic along UPRR (Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day).

East Gilroy

Land uses include farms with scattered single-family homes. For most of this RSA, there are no existing rail vibration sources and the existing low-level vibration environment is primarily traffic

on rural streets. At the connection point, some receptors are exposed to the existing rail traffic along UPRR (Caltrain passenger trains, two Amtrak passenger trains, and approximately four freight trains per day).

Pacheco Pass Subsection

For most of this RSA, there are no existing rail vibration sources and the existing low-level vibration environment is primarily traffic on SR 152 and rural streets. The land uses in this subsection are quite different from the rest of the project. There are some sparsely scattered single-family homes, but much of the subsection is not inhabited. The RSA passes through two portions of the Cottonwood Creek Wildlife Area, which is not considered vibration sensitive because it is an outdoor land use. Vibration impact criteria have not been established for animals. Therefore, no vibration propagation measurements were conducted in the Pacheco Pass Subsection.

San Joaquin Valley Subsection

The vibration RSA passes Santa Nella Road/I-5 then follows Henry Miller Road to Carlucci Road. Land uses include farms with scattered single-family homes and one elementary school. For most of the San Joaquin Valley Section, there are no existing rail vibration sources and the existing low-level vibration environment is primarily traffic on rural streets. In Volta, a freight railroad line crosses the RSA. One single-family residence is within 200 feet of the existing freight railway line and in the RSA.

5.2.2 Vibration Impact Assessment

Vibration impacts were assessed according to the criteria described in Section 4.2.3 and the method, data, and assumptions described in Section 4.2.4 and Section 4.2.5, Prediction Methods.

5.2.2.1 Construction Vibration Impacts

Construction of project alternatives would require the use of equipment that would generate temporary ground-borne vibration during the construction period, with up to 2 years of continuous construction activity anticipated at any one location. The effects from construction-related vibration would be similar under all project alternatives.

Construction vibration would result in human annoyance and building damage. Human annoyance occurs when construction vibration rises above the threshold of human perception for extended periods. A threshold of 80 VdB was used to evaluate nighttime annoyance for infrequent events at residential land use, which would typically be applied to most project construction work. For sources such as pile driving, vibratory compaction and ongoing demolition work with jackhammers or hoe-rams, the frequent event criterion of 72 VdB is more appropriate. Nighttime annoyance would potentially occur as far out as 300 feet from pile- driving activities, 140 feet from vibratory compaction and 50 feet from short-duration, transient events. These activities could occur on any of the alternatives, but more likely to occur on Alternative 4.

Building damage occurs when construction activities produce waves in the ground that are strong enough to cause cosmetic or structural damage. Of the vibration-sensitive buildings along the project corridor that have been considered, the most sensitive are lightweight (wood-framed) buildings with plaster interior wall finishes, as shown in Table 4-15 for Type III structures. The potential for vibration impacts would occur near pile driving, vibratory compaction, demolition, or excavation activities near vibration-sensitive structures (building damage) or vibration-sensitive use (annoyance). Pile driving very close to buildings (within 50 feet) would be anticipated to exceed the threshold of 0.2 inch per second (in/sec) PPV and cause building damage at Type III, as shown in Table 5-26. Pile driving would only occur at limited worksites, such as the MOWF building foundations, bridge retrofit structures, and some aerial structure foundation support for any of the alternatives.

Construction of bored tunnels in the Pacheco Pass Subsection would require the use of a TBM). Ground-borne TBM vibration is often imperceptible to humans at distances greater than 100 feet and comparable to vibration from train operations. The vibration from the TBM would vary with

the diameter of the tunnel being constructed; a bigger TBM would create greater vibration than a smaller TBM. At slant distances (measured along a direct line from the TBM to a receptor of interest) less than 100 feet, the likelihood of perceptibility increases, and overall vibration levels might be expected range of 72 VdB to 80 VdB. In this range, a person in an occupied building would be aware of the vibration from the TBM, but because the TBM would be moving through the tunnel, the vibration may only last for approximately a day. At the residential building nearest to the alignment in Pacheco Pass, on Whiskey Flat Road, the tunnel depth would greater than 200 feet. At that distance, TBM vibration would be less than 64 VdB, which would not be perceptible.

Table 5-26 Construction Equipment Vibration Impact Distances (feet)

Construction Equipment	Source Vibration at 25 feet		Buffer Distances[1] and Thresholds (feet)				
	Peak Particle Velocity (PPV in/sec)	Vibration Level, L_v	Bldg. Damage (Type I) 0.5 in/sec PPV	Bldg. Damage (Type II) 0.3 in/sec PPV	Bldg. Damage (Type III) 0.2 in/sec PPV	Annoyance (Infrequent Events) 80 VdB	Annoyance (Frequent Events) 72 VdB
Impact pile driver	0.644	104	30	42	55	159	296
Vibratory pile driver	0.17	93	12	17	22	66	122
Vibratory compactor	0.21	94	14	20	26	76	140
Loaded trucks	0.076	86	7	10	13	38	71
Jackhammer	0.035	79	4	6	8	23	42
Small bulldozer	0.003	58	1	1	2	4	8
TBM	0.144	91	11	15	20	59	109

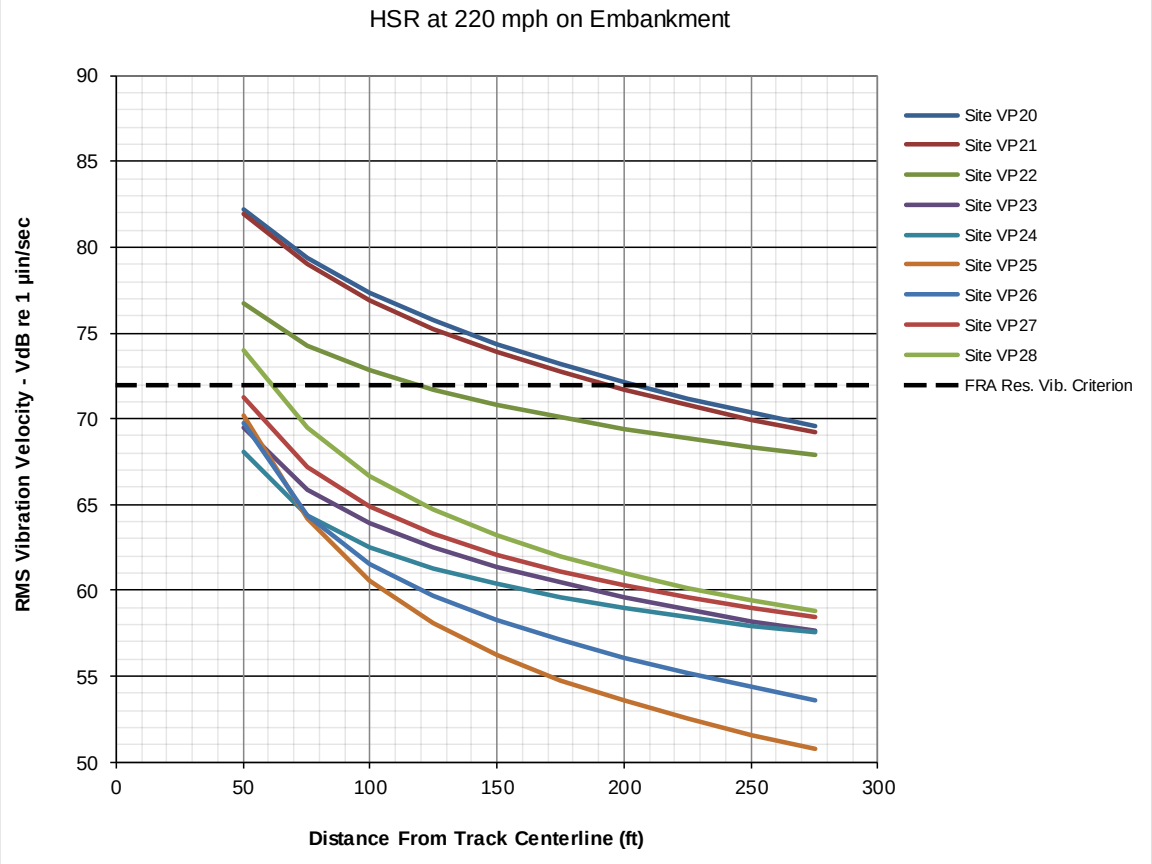
Sources: FRA 2012;
In/sec = inches per second
L_v = velocity level
VdB = velocity decibels
[1] Buffer distances calculated to the ground at the edge of structures.
Type I – Reinforced-concrete, no plaster.
Type II – Engineered concrete and masonry, no plaster
Type III – Nonengineered timber and masonry
Infrequent – less than 30 vibration events per day
Frequent – more than 70 vibration events per day

Construction key differences are discussed in Section 5.1.2.1. For the Morgan Hill and Gilroy Subsection, construction of the viaduct structure (Alternative 1 and 2) with cast-in drilled-hole piles would generally have a shorter criterion distance than the embankment and at-grade track options (Alternatives 2 and 4, respectively) because vibratory compaction would not be as widespread. For the Monterey Corridor and the San Jose Diridon Approach Subsections, the aerial viaduct (Alternatives 1 and 2) similarly would have a shorter criterion distance than Alternatives 2 and 4. Nighttime construction could be required for Alternative 4 to minimize disruption with existing passenger rail services.

5.2.2.2 Operations Vibration Impacts

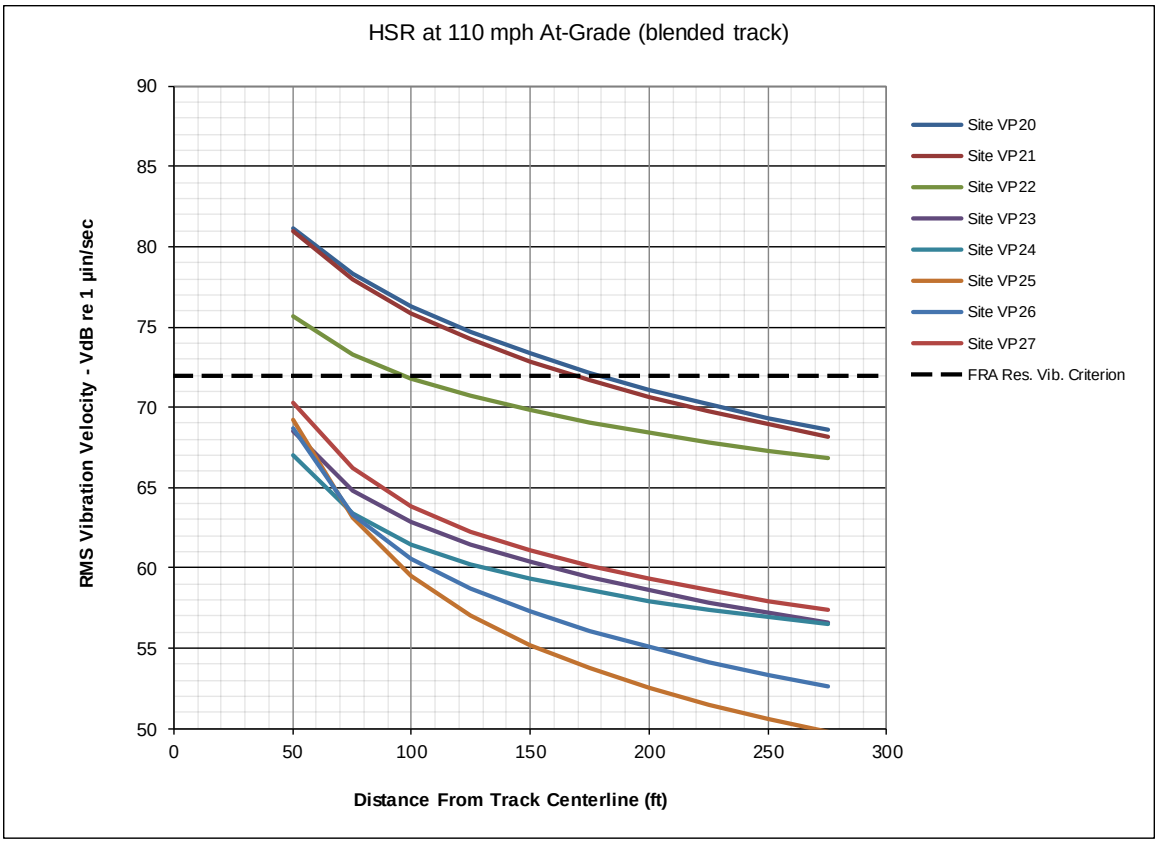
This section describes the predicted vibration impacts from project operations, which are due to annoyance. The vibration propagation measurement results were combined with the FDL data illustrated on Figure 4-10 for HSR trains and Caltrain trains, as described in Section 4.2.5.2. Figure 5-27 illustrates the projections of maximum overall ground-borne vibration levels from HSR

operations for each of the vibration propagation measurement sites assuming HSR would operate on embankment at 220 mph. The figure also includes the FRA residential vibration criterion of 72 VdB as a reference. Figure 5-28 illustrates the sample projections of maximum overall ground-borne vibration levels from HSR operations at 110 mph on blended, at-grade track for each of the vibration propagation measurement sites (excluding site VP28, where HSR would operate on dedicated tracks).



FEBRUARY 2019

Figure 5-27 Projected HSR Vibration Levels

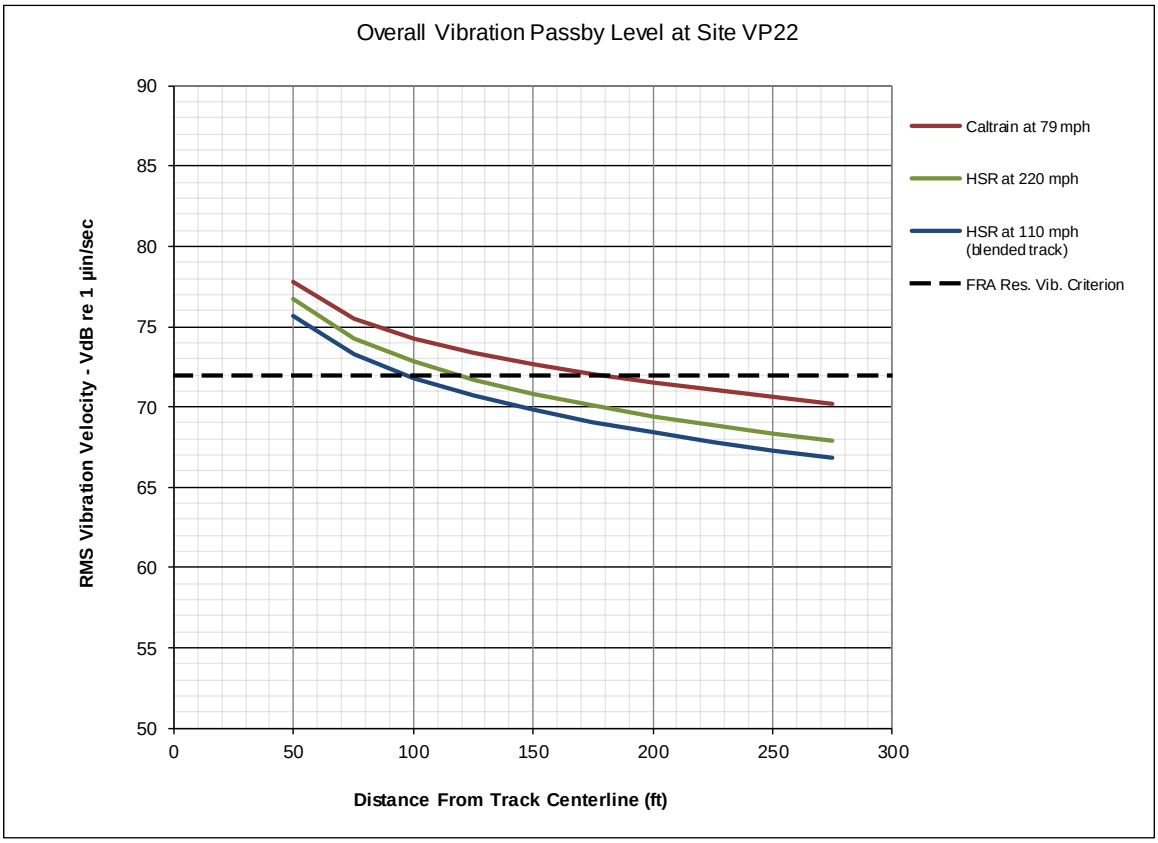


FEBRUARY 2019

Figure 5-28 Projected HSR Vibration Levels

The plots show the variation in vibration propagation throughout the RSA. The projections at the lower curves indicate much greater attenuation of vibration levels with distance compared to the higher curves. The most efficient propagation would be near McKendrie Street and near Jerome Street & Willis Avenue in San Jose. Locations in the RSA would experience different vibration levels for a train moving at the same speed because the ground conditions affect the vibration levels. At both sites, the projections for a 220-mph HSR train on embankment would be above the impact criterion within 200 feet of the track. The projections for these two sites for a 110 mph HSR train on blended at-grade track would be above the impact criterion within 170 feet of the track.

Figure 5-29 illustrates predicted HSR vibration levels at site VP22 for comparison with Caltrain vibration levels. The plot shows the vibration projections at this sample site for HSR on embankment at 220 mph and at 110 mph on blended at-grade track, in addition to projections of a Caltrain train at 79 mph (the maximum speed of Caltrain trains in the RSA with Alternatives 1, 2, and 3). As described in Section 4.2.5.2, vibration levels typically increase with increasing speed. However, even at 79 mph, the overall vibration level from a Caltrain passby is expected to be higher than from an HSR train traveling at 220 mph.



FEBRUARY 2019

Figure 5-29 Comparison of Projected HSR and Caltrain Vibration Levels

Potential vibration impacts from project operations were assessed according to the criteria described in Section 4.2.3.2. In the subsections of the vibration RSA with existing rail operations, analysts calculated the existing vibration levels and future project levels at vibration receptors. The modeled vibration levels for existing sources and shifted existing sources were calculated based on the measurement data and method discussed previously in Section 4.2.5.2. HSR vibration levels were predicted at each vibration-sensitive receptor or cluster of receptors for the project alternatives. In areas with existing train operations, the modeled existing vibration levels were compared to the modeled future project vibration levels from HSR operations and shifted existing train operations (where applicable).

The vibration impact criteria summarized in Section 4.2.3.2 are based on a maximum level of vibration from a train passby. This differs from the noise impact criteria, which are based on time-weighted metrics that account for the level of an event as well as the number of events in a specific period. Because the vibration impact criteria are based on single train passby events, a cumulative analysis was not necessary.

The vibration impact assessment was conducted for 2040.[13] HSR project operations would be fewer per day in 2029 than in 2040, but the maximum operating speeds would be the same, so

[13] A qualitative vibration impact analysis of the Interim 2025 Plus Project condition (an initial operating section of HSR service between San Jose Diridon Station to the Central Valley prior to commencement of service on the entire Phase 1 system in 2029), was also evaluated. The Interim 2025 Plus Project condition would include significantly fewer daily HSR trains than the 2029 Plus Project condition, which would be operated at the same train speeds. The vibration conditions

the maximum vibration levels would be the same for both 2029 and 2040 Plus Project conditions. Thus, the vibration impact assessment was conducted for only the 2040 Plus Project condition. Under the No Project Alternative, the Caltrain PCEP is assumed to use EMU vehicles in place of the current diesel locomotive-hauled coaches. The vibration analysis for the Caltrain PCEP assumed that the EMU vehicle would generate vibration similar to the existing vehicle (Wilson Ihrig 2014). Thus, no new vibration impacts are assumed associated with PCEP.

Table 5-27 summarizes the results of the vibration impact assessment (annoyance) by project alternative. Alternative 1 would result in 81 vibration impacts, Alternative 2 would result in 143 vibration impacts, Alternative 3 would result in 140 vibration impacts, and Alternative 4 would results in 1,203 vibration impacts. The majority of these vibration impacts would occur in the Monterey Corridor Subsection, with the remaining vibration impacts occurring in the San Jose Diridon Station Approach and Morgan Hill and Gilroy Subsections. There would be no building damage impacts from project operations.

These vibration impacts are caused by both HSR train operations and also in some cases by Caltrain operations. Where the HSR project causes Caltrain and freight tracks to be shifted closer to vibration-sensitive buildings the train operations on those closer tracks are treated as project vibration sources and compared to the impact criteria. Under Alternative 4, the project also causes Caltrain trains to operate at increased maximum speeds to accommodate blended service, and those Caltrain operations at higher speeds are treated as project vibration sources and compared to impact criteria.

Analysts also analyzed the DDV and TDV design effect on vibration effects. The vibration analysis indicated no change to the vibration impact assessment for the alternatives with the DDV and TDV. This is because the minor shifts in alignment and speed cause minor change in vibration levels.

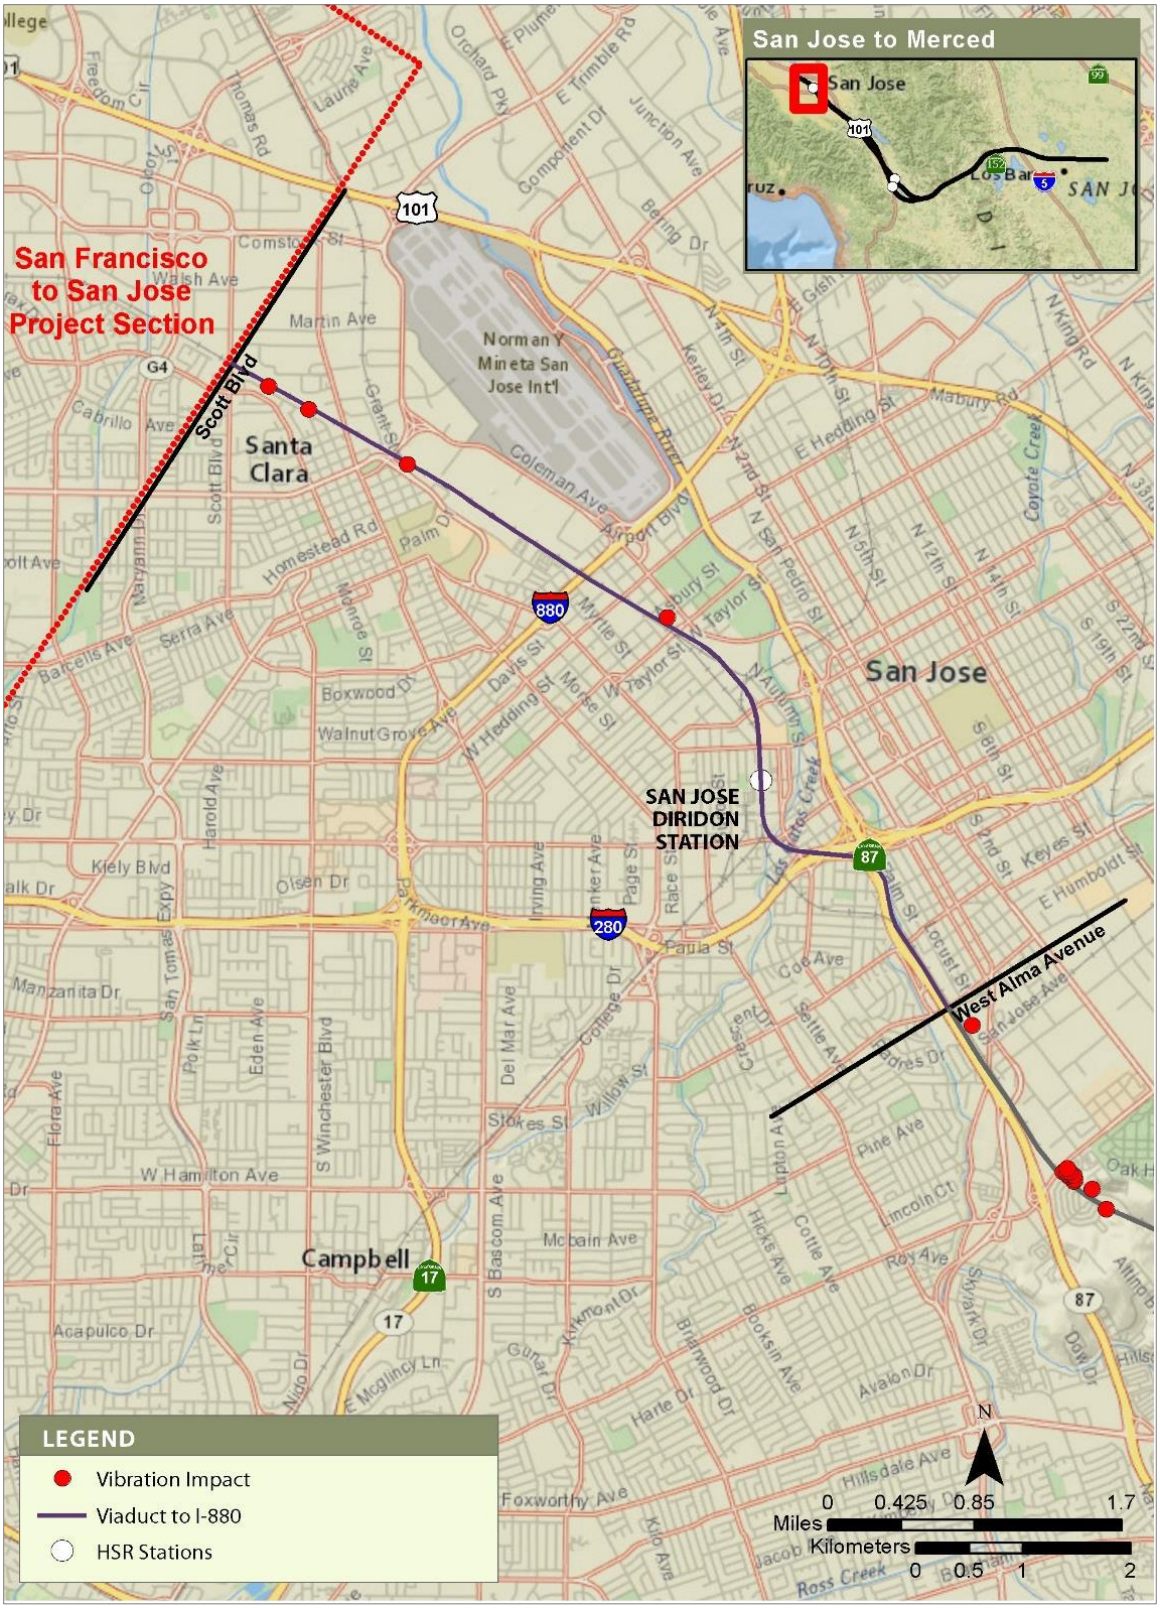
Table 5-27 2029 and 2040 Plus Project Potential Vibration Impacts

Subsection	Number of Vibration Impacts				
	Land Use Category[1]	Alternative 1	Alternative 2	Alternative 3	Alternative 4
San Jose Diridon Station Approach	2	19	78	78	201
	1, 3	0	0	0	2
Monterey Corridor	2	62	63	62	581
	1, 3	0	0	0	2
Morgan Hill and Gilroy	2	0	1	0	416
	1, 3	0	1	0	1
Pacheco Pass	2	0	0	0	0
	1, 3	0	0	0	0
San Joaquin Valley	2	0	0	0	0
	1, 3	0	0	0	0
Total	**2**	**81**	**142**	**140**	**1,198**
	1, 3	**0**	**1**	**0**	**5**

[1] FRA Land Use Categories are summarized in Table 3.4-9. Land Use Category 1 = Areas where vibration would interfere with operations; Category 2 = Residential; Category 3 = Institutional use.

from HSR operations would be the same for the 2025 and 2029 conditions. Therefore, the vibration impacts of the Interim 2025 Plus Project condition are not further addressed in this analysis.

The potential vibration impact locations for each project alternative are illustrated on Figures 5-30 through 5-39. Figures 5-30 and 5-31 show the Alternative 1 vibration impact locations, Figures 5-32 through 5-34 show the Alternative 2 vibration impact locations, Figures 5-35 and 5-36 show the Alternative 3 locations, and figures 5-37 through 5-39 show the Alternative 4 vibration impact locations. Each red dot indicates a cluster of receptors predicted to have a potential vibration impact.



FEBRUARY 2019

Figure 5-39 2029 and 2040 Plus Project Vibration Impacts—Alternative 4

Tables 5-28 through 5-31 show the vibration impact assessment results by project alternative, subsection, and segments in each subsection. The distance to the nearest vibration-sensitive receptor is shown, along with the maximum speed of HSR trains in the area. The type of existing corridor, as defined in Section 4.2.3, is listed for each location. As discussed in Section 4.2.3, the type of existing rail corridor and the existing maximum vibration levels influence the impact assessment.

The detailed vibration impact assessment results tables include the range of maximum existing vibration velocity levels that the vibration receptors are currently exposed to in each location. In the San Jose Diridon Station Approach and Monterey Corridor Subsections, there are many vibration-sensitive locations where the existing levels exceed the residential criterion of 72 VdB. Caltrain trains are the dominant existing rail source of vibration in the RSA, because Caltrain speeds exceed those of freight trains and vibration levels increase with speed. Caltrain trains create similar ground-borne vibration levels to those from HSR trains in the RSA, even though the maximum speeds are generally slower. The tables also include the range of maximum future Caltrain vibration levels. In some areas, the project alternatives would cause the existing tracks to be shifted. The analysis accounts for where the existing vibration rail sources would be shifted closer to sensitive locations.

The range of maximum vibration levels from HSR trains is provided for each location. Throughout most of the RSA the projected vibration levels from HSR trains would be below the impact criterion and typically lower than the slower Caltrain trains. Much of Alternatives 1 and 3 would be on viaduct, and vibration levels from HSR trains on aerial structure are assumed 10 VdB lower than HSR at grade or on embankments. Even though the HSR train speeds are much higher than conventional-speed commuter rail such as Caltrain, the ground-borne vibration levels are often comparable or lower. This is likely because of the relatively low input forces from the HSR trains (the FDL). To operate trains at very high speeds, the rails and wheels typically have to be in very good condition, resulting in lower vibration levels.

Four category 1 vibration-sensitive facilities were identified near the project and potential impacts at each are described in subsequent paragraphs. The FRA general assessment impact criterion of 65 VdB for Category 1 vibration-sensitive facilities was used to assess potential impacts at these buildings because it is not known what specific equipment are located in the buildings, or where any sensitive equipment is located in the buildings. Analysts used the general assessment criterion to provide a conservative assessment of potential impact. Though the specific vibration-sensitive equipment at these facilities is not known, the projected maximum 1/3-octave band vibration levels are provided for reference.

The Great Oaks Research Park would be located approximately 180 feet from the nearest HSR track in the Monterey Corridor Subsection for Alternative 4, and approximately 250 feet from the nearest HSR track for Alternatives 1, 2, and 3. The maximum projected vibration levels from HSR trains at the Great Oaks Research Park would be approximately 52 VdB with Alternatives 1 and 3, 64 VdB with Alternative 2, and 69 VdB with Alternative 4; therefore, a vibration impact is predicted under Alternative 4. With Alternatives 1 and 3, the maximum 1/3-octave band vibration level is predicted to be approximately 47 VdB. With Alternative 2, the maximum 1/3-octave band vibration level is predicted to be approximately 58 VdB. With Alternative 4, the maximum vibration in any 1/3-octave band is predicted to be approximately 63 VdB.

Two vibration-sensitive facilities were identified in the Morgan Hill and Gilroy Subsection for Alternatives 2 and 4—Paramit Manufacturing and the Butterfield Professional Center—both between Tilton Avenue and Tennant Avenue. The Paramit Manufacturing building would be approximately 215 feet from the nearest HSR track for Alternative 2 and approximately 320 feet from the nearest HSR track for Alternative 4. The maximum projected vibration levels from HSR trains would be approximately 56 VdB; therefore, no vibration impact is predicted. The maximum 1/3-octave band vibration level is predicted to be approximately 49 VdB. The Butterfield Professional Center is located approximately 75 feet from the nearest HSR track with Alternative 2 and approximately 150 feet from the nearest HSR track with Alternative 4. The maximum projected vibration levels from HSR trains would be 60 VdB for Alternative 4 and 65 VdB for Alternative 2; therefore, a vibration impact is predicted at the Butterfield facility under Alternative 2. The maximum 1/3-octave band vibration level is predicted to be approximately 59 VdB.

The St. Louise Regional Hospital would be more than 1,000 feet from the nearest HSR track in Alternative 3. The maximum projected vibration levels would be less than 50 VdB; therefore, no vibration impact is predicted.

Tables 5-28 through 5-31 also show the number of vibration impacts in each segment of each subsection. With Alternative 1, 15 single-family residences and 4 multifamily residential buildings[14] have the potential for vibration impacts and in the San Jose Diridon Station Approach Subsection between Scott Boulevard to Asbury Street. In the Monterey Corridor Subsection, there are 38 single-family residences and 24 multifamily residential buildings with the potential for vibration impacts between West Alma Avenue and Daylight Way.

Alternative 2 differs in profile and track configuration from Alternative 1 in the San Jose Station Approach Subsection. In this subsection there would be potential vibration impacts at 73 single-family residences and 5 multifamily buildings. All of these impacts would be between Scott Boulevard and Asbury Street. In the Monterey Corridor and the Morgan Hill and Gilroy Subsections, the alignment for Alternative 2 would be largely on embankment. In the Monterey Corridor Subsection, there are 39 single-family residences and 24 multifamily residential buildings with the potential for vibration impacts between West Alma Avenue and Daylight Way. In the Morgan Hill and Gilroy Subsection, there is 1 single-family residence with the potential for vibration impact between Bernal Way and Metcalf Road. Potential vibration impacts are also predicted at the Butterfield Professional Center between Tilton Avenue and Tennant Avenue.

The projected vibration impacts for Alternative 3 are the same as Alternative 2 in the San Jose Diridon Station Approach Subsection—73 single-family residences and 5 multifamily buildings. In the Monterey Corridor Subsection the projected impacts are the same as Alternative 1—38 single-family residences and 24 multifamily residential buildings between West Alma Avenue and Daylight Way.

With Alternative 4, HSR trains would operate between San Jose and Gilroy on tracks that are shared with Caltrain, other passenger trains, and freight trains, which would cause increased vibration levels compared to other alternatives. In the San Jose Station Approach Subsection, there would be potential vibration impacts at 144 single-family residences, 56 multifamily residential buildings, 1 institutional building, and 1 place of worship, and 1 hotel. In the Monterey Corridor Subsection, potential vibration impacts are predicted at 479 single-family residences, 97 multifamily residential buildings, 1 Fire Dept., 4 hotels, 1 Place of Worship, and at the Great Oaks Research Park. In the Morgan Hill and Gilroy Subsection, potential vibration impacts are predicted at 297 single-family residences, 119 multifamily residential buildings, and 1 hospital. The greater number of vibration impacts under Alternative 4 are due to both HSR trains operating on blended tracks that are typically at-grade and due to increased speeds of Caltrain trains for Alternative 4.

In the areas categorized as a heavily used rail corridor in the San Jose Diridon Station Approach Subsection, many of the receptors currently experience vibration levels greater than the criterion of 72 VdB. The project alternatives would more than double the number of train passby events per day, therefore causing vibration impacts from the project alternatives. The predicted vibration impacts in the subsections characterized as a moderately used rail corridor are primarily caused by HSR trains on embankment that exceed the vibration impact criterion or by shifted existing rail sources that exceed the criteria, though HSR train vibration does exceed the criterion at some locations.

In the Pacheco Pass Subsection, the alignment would largely be in a tunnel. The tunnel depth would vary depending upon the terrain elevation. Near the closest sensitive buildings, the tunnel would be more than 200 feet deep and 1,000 feet away horizontally. At these large distances and depths, ground-borne vibration would be well below the impact criteria. Similarly, at the depth and distance from the tunnel to the sensitive buildings in Pacheco Pass, ground-borne noise levels would be expected to be below 25 dBA, well below the impact criteria. There is also a planned cut-and-cover tunnel area of the alignment as it passes under US 101 for Alternative 2 in Morgan Hill and Gilroy Subsection. At receptors in this location, the projected ground-borne noise levels would also be expected to be below 25 dBA, well below the criteria.

[14] The number of dwelling units in each potentially affected multifamily residential building is not specified.

[1] Maximum overall vibration velocity levels (VdB re: 1 µin/sec). The ranges shown for the vibration levels in this table are a composite of many receptors and are meant to provide the limits of these values for each geographic location. The data represent the range for vibration-sensitive receptors.
[2] Locations listed as new rail corridors are not adjacent to existing tracks, therefore no corresponding existing or future Caltrain vibration levels are listed.
[3] The vibration impacts in the San Jose Diridon Station Approach Subsection with Alternative 4 are caused by Caltrain trains with increased maximum speed up to 110 mph and by HSR trains.
[4] The vibration impacts in the Monterey Corridor Subsection with Alternative 4 are caused by Caltrain trains with increased maximum speed up to 110 mph and by HSR trains.
[5] Vibration impact is projected at one non-residential vibration sensitive facility in the Monterey Corridor Subsection between Blossom Hill Road to Bernal Way with Alternative 4 at the Great Oaks Research Park caused by HSR trains.
[6] The vibration impacts in the Morgan Hill and Gilroy Subsection with Alternative 4 are caused by Caltrain trains with increased maximum speed up to 110 mph and by HSR trains.
[7] Maximum existing vibration levels and future non-HSR train vibration levels are from freight trains.

5.3 Summary of Impacts

The noise and vibration impacts for the four project alternatives are shown in Table 5-32 for both the construction phase and operations phase.

5.3.1 Noise

5.3.1.1 Construction Noise

Construction of the project would require the use of mechanical equipment that would generate temporary increases in noise and result in temporary construction impacts at noise-sensitive locations. For typical track construction scenarios, the residential nighttime 8-hour L_{eq} criterion of 70 dBA would potentially be exceeded up to 374 feet from the clear-and-grub construction activity and as far away as 774 feet from the concrete pour aerial structure activity; for the PG&E upgrades, these criteria would be exceeded as far away as 522 feet from the conductor installation construction activity. These distances would be applicable to all four project alternatives. The Authority and its contractors would comply with FTA and FRA guidelines for minimizing noise impacts at sensitive receptors during project construction (NV-IAMF#1), but construction noise impacts would remain. Distances to potential construction noise impacts for various types of activity would be the same for all alternatives.

5.3.1.2 Operations Noise

Project operations would permanently increase noise levels above the ambient noise environment at sensitive receptors. Alternative 4 would have the most severe and moderate operations noise impacts, followed by Alternative 2, Alternative 1, and Alternative 3, and impacts would be greater under the 2040 Plus Project condition compared to 2029. Under the 2040 Plus Project condition without the DDV and TDV, there would be 337 severe noise impacts and 1,200 moderate impacts under Alternative 1, 755 severe impacts and 1,844 moderate impacts under Alternative 2, 222 severe impacts and 834 moderate impacts under Alternative 3, and 1,212 severe impacts and 1,666 moderate impacts under Alternative 4. Under the 2040 Plus Project cumulative condition without the DDV and TDV, there would be 879 severe noise impacts and 2,556 moderate impacts under Alternative 1, 1,237 severe impacts and 1,932 moderate impacts under Alternative 2, 647 severe impacts and 2,357 moderate impacts under Alternative 3, and 1,589 severe impacts and 1,933 moderate impacts under Alternative 4.

With the DDV and TDV under the 2040 Plus Project condition, there would be 347 severe noise impacts and 1,195 moderate impacts under Alternative 1, 766 severe impacts and 1,838 moderate impacts under Alternative 2, 233 severe impacts and 845 moderate impacts under Alternative 3, and 1,224 severe impacts and 1,658 moderate impacts under Alternative 4. Under the 2040 Plus Project cumulative condition with the DDV and TDV, there would be 890 severe noise impacts and 2,550 moderate impacts under Alternative 1, 1,249 severe impacts and 1,925 moderate impacts under Alternative 2, 658 severe impacts and 2,361 moderate impacts under Alternative 3, and 1,601 severe impacts and 1,928 moderate impacts under Alternative 4.

Project operations would generate traffic and associated noise at HSR stations. Near the San Jose Diridon Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 29 dBA. Near the Downtown Gilroy Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 40 dBA. Near the East Gilroy Station, the largest L_{dn} contribution from the parking facilities at the nearby noise receptors would be 28 dBA. The additional noise from parking facilities would be substantially lower (at least 18 dB less) than the projected L_{dn} from HSR operations.

Project operations would also generate additional noise associated with train movements in and out of the MOWF near Gilroy. Under Alternatives 1 and 2, the L_{dn} contribution from the South Gilroy MOWF at that nearest receptor would be 40 dBA (more than 20 dBA less than HSR operations). Under Alternative 3, the L_{dn} contribution from the East Gilroy MOWF at that nearest receptor would be 47 dBA, more than 20 dB less than the HSR operations contribution at that receptor. The nearest receptors to the Alternative 4 South Gilroy MOWF would be approximately

900 feet away. In this neighborhood, the highest L_{dn} contribution from the MOWF would be 45 dBA, more than 18 dB less than the HSR operations contribution at that receptor.

Project construction would result in permanent changes in the local roadway network that would require some diversion and rerouting of traffic. The diversion of traffic would not be expected to affect noise levels because traffic on local roadways provides only a minor contribution to overall noise levels.

Project operations would generate additional traffic and traffic-related noise under the 2029 Plus Project and 2040 Plus Project conditions. Permanent increases in traffic-related noise would be similar for all four alternatives and would occur at roadways segments near San Jose Diridon Station, along Monterey Corridor, and near Gilroy. In 2029, seven roadway segments under Alternatives 1 and 2 and six roadway segments under Alternatives 3 and 4 would have the potential for noise level increases greater than or equal to 3 dB, compared to existing noise conditions. In 2040, operations of all project alternatives would result in 12 roadway segments with the potential for noise level increases greater than or equal to 3 dB. The majority of these traffic noise impacts would occur near the San Jose Diridon Station and along Monterey Road.

The potential for passing HSR train noise to startle or surprise humans near the HSR track and to result in human annoyance was determined to be unlikely for dedicated sections of the alignment and at one location for blended service in Morgan Hill under Alternative 4. Analysts also evaluated the potential for livestock to experience stress associated the noise of passing trains in exceedance of the FRA's recommended threshold. Where livestock operations are within approximately 30 feet of the edge of the HSR right-of-way, adverse effects would occur within 30 feet of the HSR right-of-way. In locations where HSR trains are sounding warning horns, livestock within approximately 285 feet of HSR tracks could experience adverse effects.

Substation operations would not generate additional noise impacts when compared to the operations train noise impacts that exceed FRA criteria. Under Alternative 4, the combined train and TPSS operations would generate severe noise impacts at 30 apartment residences; moderate noise impacts would occur for Alternates 2, 3, and 4. The greatest impacts would occur along Alternative 4, followed by Alternative 1 and 3, and with Alternative 2 having the fewest impacts. The difference in substation noise impacts among the project alternatives is predominately the result of site placement of TPSS or paralleling station sites; the Alternative 4 San Jose TPPS site would be directly adjacent to a large multifamily apartment building.

5.3.2 Vibration

5.3.2.1 Construction Vibration

Construction of the project alternatives would result in vibration impacts potentially causing human annoyance and building damage. Most construction activities would only cause annoyance from vibration within 160 feet of the mechanical equipment. Some equipment, such as pile driving or ongoing demolition work would have the potential to cause annoyance from vibration within 300 feet. Buildings close to pile-driving activity (within 50 feet) would have the potential for structural damage. Incorporation of NV-IAMF#1 would minimize construction vibration and the potential for it to cause annoyance or damage to buildings. However, even with NV-IAMF#1, some sensitive receptors would still be exposed to ground-borne vibration that could result in annoyance or building damage.

Construction of tunnels in the Pacheco Pass Subsection would result in human-perceptible vibration in occupied buildings within approximately 100 feet of TBM operations; however, the tunnel depth near the closest occupied building would be more than 200 feet. Near the closest sensitive buildings, the tunnel would be more than 200 feet deep and 1,000 feet away horizontally. At these large distances and depths, ground-borne vibration would be well below the impact criteria. Similarly, at the depth and distance from the tunnel to the sensitive buildings in Pacheco Pass, ground-borne noise levels are expected to be below 25 dBA, thus below the lowest impact criteria. There is also a planned cut-and-cover tunnel area of the alignment as it passes under US 101 for Alternatives 1 and 2 in Morgan Hill and Gilroy Subsection. At receptors

in this location, the projected ground-borne noise levels are expected to be below 25 dBA, also below the lowest impact criteria. At these distances, it is not anticipated that vibration from the TBM would be an issue.

5.3.2.2 Operations Vibration

Project operations would cause permanent vibration impacts (annoyance) at sensitive receptors. Alternative 1 would result in 81 vibration impacts, Alternative 2 would result in 143 vibration impacts, Alternative 3 would result in 140 vibration impacts, and Alternative 4 would result in 1,203 vibration impacts. Under Alternatives 1-3, the majority of these vibration impacts would occur in the San Jose Diridon Station Approach and the Monterey Corridor Subsections, with the remaining vibration impacts occurring in the Morgan Hill and Gilroy Subsection. Under Alternative 4, the majority of the vibration impacts would occur in the Monterey Corridor and Morgan Hill and Gilroy Subsections, with the remaining vibration impacts occurring in the San Jose Diridon Station Approach Subsection. Project operations would not have the potential to cause building damage because the vibration levels would not approach damage thresholds. See Section 4.2.1, Descriptors, for additional discussion.

Table 5-32 Summary of Impacts

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Construction-Related Noise				
Construction noise impacts	Temporary noise impacts at noise sensitive locations would exceed the residential nighttime 8-hour L_{eq} criterion of 70 dBA for typical track construction activities up to 374 feet from the clear-and-grub construction activity and up to 774 feet from the concrete pour aerial structure activity. For the PG&E upgrades, these criteria would be exceeded as far away as 522 feet from reconductoring activity. These distances would be applicable to all four project alternatives.	Similar to Alternative 1, with fewer noise impacts in Morgan Hill and Gilroy and Monterey Corridor Subsections.	Similar to Alternative 1, without noise impacts on downtown Gilroy businesses.	Similar to Alternative 1, but no concrete pour aerial structure activity from San Jose to Gilroy. This would have more impacts in Morgan Hill.
Operations-Related Noise				
2029 Plus Project operations noise impacts	▪ 310 (313) moderate impacts ▪ 47 (51) severe impacts	▪ 599 (601) moderate impacts ▪ 38 (43) severe impacts	▪ 227 (233) moderate impacts ▪ 34 (37) severe impacts	▪ 1,001 (1,004) moderate impacts ▪ 190 (197) severe impacts

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
2040 Plus Project operations noise impacts	▪ 1,200 (1,195) moderate impacts ▪ 337 (347) severe impacts	▪ 1,844 (1,838) moderate impacts ▪ 755 (766) severe impacts	▪ 834 (845) moderate impacts ▪ 222 (233) severe impacts	▪ 1,666 (1,658) moderate impacts ▪ 1,212 (1,224) severe impacts
2029 Plus Project cumulative operations noise impacts	▪ 1,620 (1,623) moderate impacts ▪ 71 (75) severe impacts	▪ 1,426 (1,427) moderate impacts ▪ 200 (205) severe impacts	▪ 1,306 (1,312) moderate impacts ▪ 48 (51) severe impacts	▪ 1,500 (1,496) moderate impacts ▪ 475 (501) severe impacts
2040 Plus Project cumulative operations noise impacts	▪ 2,556 (2,550) moderate impacts ▪ 879 (890) severe impacts	▪ 1,932 (1,925) moderate impacts ▪ 1,237 (1,249) severe impacts	▪ 2,357 (2,361) moderate impacts ▪ 647 (658) severe impacts	▪ 1,933 (1,928) moderate impacts ▪ 1,589 (1,601) severe impacts
Annoyance from onset of HSR passby	Operations would not cause human annoyance from the startle effect of HSR train passbys within dedicated sections of the alignment because the threshold for sudden onset noise would occur within the right-of-way, which would be fenced to prohibit public access			Operations would cause initial human annoyance from the startle effect of HSR train passbys at one location within 23 feet of the tracks in Morgan Hill. Effects south and east of Gilroy would be the same as Alternatives 1, 2 and 3.
HSR station noise	Noise contribution from parking facilities: ▪ 29 dBA L_{dn} at San Jose Diridon Station ▪ 40 dBA L_{dn} at the Downtown Gilroy Station This additional noise would be substantially lower than noise from HSR trains.	Noise contribution from parking facilities: ▪ 29 dBA L_{dn} at San Jose Diridon Station ▪ 40 dBA L_{dn} at the Downtown Gilroy Station This additional noise would be substantially lower than noise from HSR trains.	Noise contribution from parking facilities: ▪ 29 dBA L_{dn} at San Jose Diridon Station ▪ 28 dBA L_{dn} at the East Gilroy Station This additional noise would be substantially lower than noise from HSR trains.	Noise contribution from parking facilities: ▪ 29 dBA L_{dn} at San Jose Diridon Station ▪ 40 dBA L_{dn} at the Downtown Gilroy Station This additional noise would be substantially lower than noise from HSR trains.
Maintenance facility noise	40 dBA L_{dn} contribution from train movements at the South Gilroy MOWF, substantially lower than the noise from operating HSR trains. No additional impact is projected.		47 dBA L_{dn} contribution from train movements at the East Gilroy MOWF, substantially lower than the noise from operating HSR trains. No additional impact is projected.	45 dBA L_{dn} contribution from train movements at the Alternative 4 MOWF, substantially lower than the noise from operating HSR trains. No additional impact is projected.

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
2029 Plus Project traffic-related noise increases	Roadway segments with an anticipated increase in traffic noise of 3 dB or greater: ▪ 4 roadway segments near the San Jose Diridon Station ▪ 2 roadway segments along Monterey Road ▪ 1 roadway segment near the South Gilroy MOWF		Roadway segments with an anticipated increase in traffic noise of 3 dB or greater: ▪ 4 roadway segments near the San Jose Diridon Station ▪ 2 roadway segments along Monterey Road	Roadway segments with an anticipated increase in traffic noise of 3 dB or greater: ▪ 3 roadway segments near the San Jose Diridon Station ▪ 3 roadway segments along Monterey Road
2040 Plus Project traffic-related noise increases	Roadway segments with an anticipated increase in traffic noise of 3 dB or greater: ▪ 5 roadway segments near the San Jose Diridon Station ▪ 6 roadway segments along Monterey Road ▪ 1 roadway segment near the South Gilroy MOWF		Roadway segments with an anticipated increase in traffic noise of 3 dB or greater: ▪ 5 roadway segments near the San Jose Diridon Station ▪ 6 roadway segments along Monterey Road ▪ 1 roadway segment near the East Gilroy MOWF	Roadway segments with an anticipated increase in traffic noise of 3 dB or greater: ▪ 4 roadway segments near the San Jose Diridon Station ▪ 6 roadway segments along Monterey Road ▪ 1 roadway segment near the Downtown Gilroy Station ▪ 1 roadway segment near the South Gilroy MOWF
Noise effects on livestock	Livestock within approximately 30 feet of the edge of the HSR right-of-way would experience stress associated with exposure to noise levels above the recommended thresholds for passbys (all alternatives). Livestock within approximately 285 feet of the edge of the HSR right-of-way would experience stress associated with exposure to noise levels from sounding of HSR horns (Alternative 4 only).			
Traction power facility noise	The substation facilities would generate noise but would not incur additional noise impact beyond those from trains and horns.	Same as Alternative 1	Same as Alternative 1	Same as Alternative 1

Effect	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Construction-Related Vibration				
Construction vibration impacts	Potential annoyance from nighttime vibratory methods within 300 feet of residential structures. Potential building damage from impact pile driving within 50 feet of structures.	Similar to Alternative 1, but potentially with more vibratory compaction at embankments and at grade in Morgan Hill and Gilroy and Monterey Corridor Subsections; less vibratory compaction in San Jose to Scott Boulevard touchdown.	Similar to Alternative 1 to Gilroy and in Monterey Corridor Subsection, but eastern alignment in Gilroy and Morgan Hill Subsection would affect fewer structures; similar to Alternative 2 from Monterey through San Jose.	Similar Alternative 1 east of Gilroy; most vibratory compaction at embankments and at grade of all alternatives; construction within existing right-of-way could require more nighttime work to minimize service disruptions.
Construction TBM vibration impacts	Potential perceptible vibration in occupied buildings within 100 feet of TBM operations for tunnel construction. Tunnel depth at closest occupied building is greater than 200 feet, so vibration from TBM not anticipated to be an issue.			
Operations-Related Vibration				
Operations vibration impacts	81 permanent vibration impacts	143 permanent vibration impacts	140 permanent vibration impacts	1,203 permanent vibration impacts

L_{eq} = sound level equivalent
dBA = A-weighted decibel
PG&E = Pacific Gas and Electric
HSR = high-speed rail
mph = miles per hour
UPRR = Union Pacific Railroad
L_{dn} = day-night sound level
MOWF = maintenance of way facility
dB = decibel
TBM = tunnel boring machine
Impacts associated with the design variants are shown in parentheses. The DDV affects Alternative 4 within the San Jose Diridon Station Approach Subsection; the TDV affects all alternatives within the Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.

APPENDIX 3.4-B: NOISE AND VIBRATION MITIGATION GUIDELINES

Memorandum

DATE: March 8, 2018

TO: Regional Consultants (RCs) and Engineering and Environmental Consultants (EECs)

FROM: Bryan Porter and Rob Greene

CC: Scott Rothenberg and Vera Bezdicek

SUBJECT: Updated Noise Mitigation Guidance; Cost for Benefited Residence

---

Consistent with an approach used by the California Department of Transportation (Caltrans), the Authority in 2011 adopted criteria to determine the reasonableness of building noise barriers to mitigate severe noise impacts associated with operation of the train. In that guidance, the Authority specified it would build a barrier if the cost range was within $55,000 (2010$) per benefited residence. This amount was consistent with the 2010 Caltrans allowance. Based on the annual construction price index, Caltrans has recently updated its policy (February 2018) and increased the cost allowance to $95,000 (2018$). For continued consistency with Caltrans, the Authority's Noise Mitigation Guidelines have been updated. In addition, the guidelines have been amended to read that the "reasonable allowance for the noise barriers will be calculated using the Caltrans base cost allowance in effect at the time of implementation of the noise mitigation measure." This version supersedes earlier guidance first issued in 2011 and revised in April 2017.

Should you have any questions, please contact Bryan Porter at Bryan.Porter@hsr.ca.gov or Rob Greene at Rob.Greene@wsp.com.

Authority Noise Mitigation Guidelines (Rev. 03/2018)

DRAFT

Attachment

Noise Mitigation Guidelines (Rev. 03/2018)

In general, noise mitigation must be considered when impacts are identified. Mitigation guidelines for the three impact categories identified by FRA are as follows:

- No Impact: No mitigation required.
- Moderate Impact: Mitigation may be considered at the discretion of the Authority, and implementation would be subject to reasonable project-specific factors related to effectiveness, cost, density, and proximity of sensitive receivers.
- Severe Impact: Consideration of mitigation is required if impacts cannot be avoided. The Authority will take steps to reduce noise substantially through mitigation measures that are reasonable, physically feasible, practical, and cost-effective.

Mitigation of Severe Noise Impacts

The Authority will examine alternatives to avoid, minimize, or mitigate severe noise impacts. If severe noise impacts cannot be avoided, then the Authority will take steps to reduce severe noise substantially through mitigation measures that are reasonable, physically feasible, practical, and cost-effective. The following criteria will be used for evaluating the reasonableness of noise barriers as mitigation for severe noise impacts:

- Calculations and Computations for barrier geometry as stated in the FRA High Speed Noise and Vibration assessment, Table 5-3.
- Increase over existing noise levels.
- Number of noise sensitive sites affected.
- The minimum number of affected sites should be at least 10, and the length of a noise barrier should be at least 800 feet.
- Barrier heights up to a maximum of 14 feet will be considered. Mitigation options for areas that require barriers over 14 feet will be studied on a case-by-case basis.
- The "reasonable allowance" for the noise barriers is calculated using the Caltrans base cost allowance for the current year, which is published at http://www.dot.ca.gov/hq/env/noise/.
- The community should approve of implementation of the recommended noise barriers (75% of all affected parties).

Section 4(f) and Section 106 properties with severe or moderate noise impacts will require mitigation, will not be subject to these guidelines, and will be evaluated on a case-by-case basis.

Substantial Noise Reduction

A minimum outdoor noise reduction of 5 decibels (dB) using the applicable criterion for the property is considered substantial.

DRAFT

Reasonable

Reasonableness implies that good judgment and common sense have been applied during the decision-making process. Reasonableness is determined on the basis of several factors regarding the individual circumstances and the specific needs of affected receivers.

Physically Feasible

Noise mitigation measure must be designed, constructed, installed, or implemented in compliance with structural requirements related to ground conditions, wind loading, seismic risk, safety considerations, accessibility, material maintainability and longevity, and applicable engineering design practices and technology. Noise mitigation measures must not result in an adverse environmental impact, such as significant visual intrusions, blocked views, or adverse effects to a historical site.

Sound barriers are the most common noise mitigation measure. The maximum sound barrier height would be 14 feet for at-grade sections; however, all sound barriers should be designed to be as low as possible to achieve a substantial noise reduction. Berm and berm/wall combinations are the preferred types of sound barriers where space and other environmental constraints permit.

On aerial structures, the maximum sound barrier height would also be 14 feet, but barrier material would be limited by engineering weight restrictions for barriers on the structure. Sound barriers on the aerial structure should still be designed to be as low as possible to achieve a substantial noise reduction.

Visual Effects

Noise mitigation measures must be designed, constructed, installed, and implemented in a manner that does not result in adverse impacts to the visual resources in the area. Sound barriers will consist of a solid barrier no more than 6 feet in height. Above 6 feet, the sound barrier will be made of transparent materials. For example, a 13-foot-high sound barrier would consist of 6 feet of solid material on the bottom topped by 7 feet of transparent material.

Cost Effectiveness

Two factors are required to determine cost effectiveness of mitigation by noise barriers: the unit construction cost and the number of benefited receptors.[1] The cost for constructing a noise barrier along the at-grade portion of the alignment is estimated to be $70.00 per square foot, and the cost to construct a noise barrier along the elevated portion of the alignment is $65.00 per square foot. The total cost of mitigation cannot exceed $95,000 per benefitted receiver. This cost is determined by dividing the total cost of the mitigation measure by the number of noise-sensitive buildings that receive a substantial (i.e., 5 dBA or greater) outdoor noise reduction. This calculation will generally limit the use of mitigation in rural areas that have few and/or isolated residential buildings. If the density of residential dwellings is insufficient to make the measure cost-effective, then other noise abatement measures, such as sound insulation, will be considered on a case-by-case basis. If sound insulation is identified as an alternative mitigation measure, the treatment must provide a substantial increase in noise reduction (i.e., 5 dBA or greater) between the outside and inside noise levels for interior habitable rooms.

[1] The unit construction cost for high-speed rail barriers is based on an evaluation of the special design requirements established by the California High-Speed Rail Authority policy regarding noise barrier mitigation. The typical base cost for transportation noise abatement screen-wall type barriers is available from the Federal Highway Administration's (FHWA) national inventory of noise barriers, Caltrans, qualified barrier manufacturers, and construction cost historical databases. These sources in (2016/2017 dollars) were used to estimate probable costs per square foot for typical high-speed rail noise barriers that incorporate opaque and transparent materials. The estimate of probable costs for barriers having special requirements (e.g., special foundations, highly curved sections, higher than standard height, etc.) should be evaluated on an individual basis.

Mitigation Parameters

- Prior to operation of the HST the Authority will install sound barriers where they can achieve between 5 and 15 dB of noise reduction, depending on their height and location relative to the tracks. The primary requirements for an effective sound barrier are that the barrier must (1) be high enough and long enough to break the line-of-sight between the sound source and the receiver, (2) be of an impervious material with a minimum surface density of 4 pounds per square foot, and (3) not have any gaps or holes between the panels or at the bottom. Because many materials meet these requirements, aesthetics, durability, cost, and maintenance considerations usually determine the selection of materials for sound barriers (examples are shown in Figure 3.4-14). Depending on the situation, sound barriers can become visually intrusive. Typically, the sound barriers style is selected with input from the local jurisdiction to reduce the visual effect of barriers on adjacent lands uses. For example, sound barriers could be solid or transparent, and made of various colors, materials, and surface treatments.

- The Authority will work with the communities to identify how the use and height of sound barriers would be determined using jointly developed performance criteria. Other solutions may result in higher numbers of residual impacts than reported herein. Options may be to reduce the height of sound barriers and combine barriers with sound insulation or to accept higher noise thresholds than the FRA's current noise thresholds.

- If sound walls are not proposed or do not reduce sound levels to below a severe impact level, building sound insulation can be installed. Sound insulation of residences and institutional buildings to improve the outdoor-to-indoor noise reduction is a mitigation measure that can be provided when the use of sound barriers is not feasible in providing a reasonable level (5 to 7 dB) of noise reduction. Although this approach has no effect on noise in exterior areas, it may be the best choice for sites where sound barriers are not feasible or desirable and for buildings where indoor sensitivity is of most concern. Substantial improvements in building sound insulation (on the order of 5 to 10 dB) can often be achieved by adding an extra layer of glazing to windows, by sealing holes in exterior surfaces that act as sound leaks, and by providing forced ventilation and air conditioning so that windows do not need to be opened. Performance criteria would be established to balance existing noise events and ambient roadway noise conditions as factors for determining mitigation measures.

- If sound walls or sound installation is not effective, the Authority can acquire easements on properties severely affected by noise. Another option for mitigating noise impacts is for the authority to acquire easements on residences likely to be impacted by HST operations in which the homeowners would accept the future noise conditions. This approach is usually taken only in isolated cases where other mitigation options are infeasible, impractical, or too costly.

- The decision to include mitigation assessments may depend on factors such as the number of noise-sensitive sites affected, the relative increase in noise levels, the sensitivity at affected land uses, the effectiveness of mitigation measures, community views, costs versus benefits, design limitations, whether sensitive use is solely indoors, and safety. For example, where land-use activity is solely indoors, an interior Ldn criterion of 45 decibels A-weighted (dBA) from project sources is recommended to determine whether building sound insulation improvements should be considered for mitigation.

Such mitigation measures should be included in the Authority's Division of Real Property appraisals as a cost to cure through physical modifications to the improvement or the purchase of sound easements, as appropriate.

FTA / FRA Construction Noise Mitigation

1. <u>Design considerations and project layout:</u>

DRAFT

- Construct noise barriers, such as temporary walls or piles of excavated material, between noisy activities and noise-sensitive receivers.
- Route truck traffic away from residential streets, if possible. Select streets with the fewest homes, if no alternatives are available.
- Site equipment on the construction lot as far away from noise-sensitive sites as possible.
- Construct walled enclosures around especially noisy activities or around clusters of noisy equipment. For example, shields can be used around pavement breakers and loaded vinyl curtains can be draped under elevated structures.

2. Sequence of operations:

- Combine noisy operations so they occur in the same time period. The total noise level produced will not be significantly greater than the level produced if the operations were performed separately.
- Avoid nighttime activities. Sensitivity to noise increases during the nighttime hours in residential neighborhoods.

3. Alternative construction methods:

- Avoid impact pile driving where possible in noise-sensitive areas. Drilled piles or the use of a sonic or vibratory pile driver are quieter alternatives where the geological conditions permit their use.
- Use specially quieted equipment, such as quieted and enclosed air compressors, and mufflers on all engines.
- Select quieter demolition methods, where possible. For example, sawing bridge decks into sections that can be loaded onto trucks results in lower cumulative noise levels than impact demolition by pavement breakers.
- The environmental assessment should include a description of one or more mitigation approach for each affected location.

FTA / FRA Construction Vibration Mitigation

1. Design considerations and project layout:

- Route heavily loaded trucks away from residential streets, if possible. Select streets with fewest homes, if no alternatives are available.
- Operate earthmoving equipment on the construction lot as far away from vibration-sensitive sites as possible.

2. Sequence of operations:

- Phase demolition, earthmoving, and ground-impacting operations so as not to occur in the same time period. Unlike noise, the total vibration level produced could be significantly less when each vibration source operates separately.
- Avoid nighttime activities. People are more aware of vibration in their homes during the nighttime hours.

DRAFT

3. Alternative construction methods:

    - Avoid impact pile driving where possible in vibration-sensitive areas. Drilled piles or the use of a sonic or vibratory pile driver causes lower vibration levels where the geological conditions permit their use.

    - Select demolition methods not involving impact, where possible. For example, sawing bridge decks into sections that can be loaded onto trucks results in lower vibration levels than impact demolition by pavement breakers, and milling generates lower vibration levels than excavation using clam shell or chisel drops.

    - Avoid vibratory rollers and packers near sensitive areas.

Construction Noise and Vibration Mitigation Guidelines

All construction activities in this report were analyzed in terms of their noise impacts in regards to FRA recommended guidelines. Local jurisdictions provide construction noise exempt times where the FRA guidelines are followed. A majority of construction will be conducted during these construction noise exempt times, but when construction is conducted outside of the construction noise exempt times, construction noise must abide by local noise standards. Proper mitigation may be necessary in order to avoid noise impacts at nearby noise-sensitive receivers.

Pile driving activities conducted during the grade separation and elevated track structure construction phases would be the loudest noise generating activity during construction of the high speed train corridor. As previously mentioned, residences within a distance of 410 feet of grade separation construction activities that include pile driving, or within 430 feet of elevated track structure construction activities that include pile driving, would be exposed to noise levels greater than the 80 dBA Leq threshold.

- Piles that are required for structure along the HST corridor and which would be located within 500 feet of a noise sensitive receiver should be installed using the drilling and casing method.

If the drilling and casing method were used, maximum noise levels associated with construction activities would drop by 11 dB, and the distances to the 80 dBA Leq contour would decrease from 410 feet to 180 feet for grade separation construction activities, and decrease from 430 feet to 220 feet for elevated track structure construction activities. Another method to mitigate noise related to pile driving is the use of an augur to install the piles instead of a pile driver which would reduce noise levels substantially. If pile driving is necessary, limit the time of day the activity can occur.

The most effective way to minimize the impact of construction noise during the development of the project is to enforce the time restrictions for the hours of construction as listed in local noise ordinances. It is important for the design engineer to plan the order of operations during construction so that the noise levels resulting from construction operations will not exceed local noise ordinances or those recommended by the FRA. To avoid unnecessary annoyance from construction noise, the following best practices for construction noise control should also be considered for inclusion in construction contract documents:

- All noise-producing project equipment and vehicles using internal combustion engines shall be equipped with mufflers and air-inlet silencers, where appropriate, in good operating condition that meet or exceed original factory specifications. Mobile or fixed "package" equipment (e.g., arc-welders, air compressors) shall be equipped with shrouds and noise control features that are readily available for that type of equipment.

DRAFT

- All mobile or fixed noise-producing equipment used on the project, which is regulated for noise output by a local, state, or federal agency, shall comply with such regulation while in the course of project activity.
- Material stockpiles and mobile equipment staging, parking, and maintenance areas shall be located as far as practicable from noise-sensitive receivers.
- Material stockpiles should be used to block line of site to nearby noise-sensitive receivers when possible.
- Locating fixed noise-generating equipment as far from noise-sensitive land uses as is practical.
- Limit the loudest construction activities, such as concrete breaking and jack hammering, to the middle of the day when the sensitivity to such noises will be minimal. Noise-producing signals, including horns, whistles, alarms, and bells shall be used for safety warning purposes only.
- No project-related public address or music system shall be audible at any adjacent receiver.
- If complaints arise, the contractor shall initiate a construction noise monitoring plan to ensure the construction noise levels at the nearest noise-sensitive land uses are within the limits of the noise ordinance.
- Avoid nighttime construction in residential neighborhoods.
- During nighttime work, use smart back-up alarms, which automatically adjust the alarm level based on the background level, or switch off back-up alarms and replace with spotters.
- Re-route construction-related truck traffic along roadways that will cause the least disturbance to residents.
- Implement noise-deadening measures for truck loading and operations.
- Minimize the use of generators to power equipment.
- Grade surface irregularities on construction sites.
- Use of temporary noise barriers shall be considered where project activities and equipment are unavoidably close to noise-sensitive receivers.
- Use of on-site trailers and containers as temporary barriers between any fixed construction noise source and nearby sensitive receivers.
- All workers involved with the construction of this project must be protected from excessive noise exposure as mandated by the Occupational Safety and Health Administration (OSHA), which has regulated worker noise exposure to a time-weighted-average of 90 dBA over an 8 hour work shift. Areas where levels exceed 85 dBA must be designated and labeled as high-noise-level areas where hearing protection is required.

Construction Vibration Mitigation

After locating potential vibration impacts due to construction with the use of the procedure outlined above, mitigation may be necessary to ensure that there will be no vibration impacts at sensitive receivers. Changes in the design and project layout, changes in the sequence of operations, and using alternative construction methods are all available vibration mitigation options.

DRAFT

When the engineers design the project and the layout of the project, heavily loaded trucks can be re-routed away from residential streets and onto streets with fewer homes. Earthmoving equipment on the construction lot should also be operated as far as possible from sensitive receivers. Changes in the sequence of operations can also mitigate vibration impacts at sensitive receivers. Construction activities that cause high levels of vibration should be staggered so that multiple sources of vibration are not occurring at once. Nighttime construction activities should also be avoided. Alternative construction methods are also an acceptable vibration mitigation option. If pile driving does occur, impact pile driving should be avoided near vibration-sensitive areas. A sonic or vibratory pile driver will generate lower vibration levels at sensitive receivers. Demolition methods not involving impacts should be used when possible. The utilization of vibratory rollers and packers should be avoided near vibration-sensitive receivers.

Introduction

This appendix documents measurement results from a preconstruction electromagnetic survey of locations along the San Jose to Carlucci project extent corridor. The purpose of the survey was to: (1) provide a baseline characterization of the existing electromagnetic environment, (2) allow comparisons with the expected electromagnetic footprint from the planned California High-Speed Rail (HSR) system, and (3) provide guidance for electromagnetic compatibility (EMC) requirements by defining the typical electromagnetic environment that the HSR system must operate in without interference.

Land uses, existing facilities, and infrastructure along the alignment were reviewed, with a list of approximately 30 candidate sites evaluated. This review concentrated on identifying potentially electromagnetic interference (EMI)-sensitive facilities, as well as existing electromagnetic field (EMF) sources such as power generation, power distribution, and communications facilities. The selection criteria, taken from Technical Memorandum (TM) 3.4.11, Measurement Procedure for Assessment of CHSTP Alignment EMI Footprint, favored providing a balanced coverage of:

- The geographic extent of the segment
- High-emission sites
- Low-emission sites
- Sites with high-sensitivity receptors

A final group consisting of 10 sites was selected based upon the above considerations and to provide representative coverage of land uses. Two types of measurements were performed at each location. The first involved measurement of radiated electric fields from 10 kilohertz (kHz) to 6 gigahertz (GHz), meant to characterize the radio-frequency (RF) environment. These electric field strengths were measured using an RF spectrum analyzer and calibrated antennas. Expected sources of RF signals included:

- Cell towers (cellular telephone)
- Broadcast towers (radio and television broadcasts)
- Airport radars and aircraft communications equipment
- General high-frequency and very-high-frequency fixed and mobile communications systems (e.g., police, fire, emergency medical technician, utilities, and government)
- Local wireless (wireless fidelity [WiFi] and Worldwide Interoperability for Microwave Access [WiMAX])

The second part of the test procedure involved measurements of background direct current (DC) and power frequency magnetic fields along the alignment. These magnetic fields were recorded using a three-axis fluxgate sensor with a waveform recording data acquisition system. Expected sources of DC and low-frequency magnetic fields included:

- The geomagnetic field
- High-voltage transmission lines
- Electric distribution lines
- Traction power distribution facilities
- Geomagnetic perturbations due to passing vehicles and trains

The facilities most sensitive to shifts in the DC (geomagnetic perturbations) and alternating current (AC) magnetic fields are:

- High technology semiconductor (e.g., electron microscopes [transmission electron microscopes/scanning electron microscopes], electron-beam lithography, ion-writing systems, focused ion-beam systems)
- High technology biology (e.g., nuclear magnetic resonance, magnetic resonance imaging [MRI], electron microscopes)

- Medical imaging (e.g., computed tomography [CT] scanners, MRI systems)
- University/research (instrumentation for chemistry, physics, electrical engineering, and similar systems to those mentioned for high technology and medical facilities).

Test Procedures and Equipment

Analysts characterized the RF environment along the project extent by measuring the prevailing electric field strength at each of the 10 test sites, over the frequency range from 10 kHz to 6 GHz. The RF and magnetic field measurements were performed between July 18, 2016, and July 22, 2016. Measurements were made using a vertical monopole antenna (AH Systems SAS-550-1) for the frequency range from 10 kHz to 30 MHz and a broadband bilogical antenna (AH Systems SAS-521-7) for the frequency range from 25 MHz to 6 GHz, connected to an Anritsu MS2721B Spectrum Analyzer. Measurements were made in eight contiguous frequency bands and recorded per Section 6.4 of TM 3.4.11. Where practical, the RF antennas were located approximately 50 feet from the proposed alignment.

Electric field measurement files from the spectrum analyzer include both min-hold and max-hold levels as a function of frequency across each of the measurement bands, and a complete file set will be preserved for each measurement location. Reported results include the low-frequency measurements with the omni-directional vertical monopole, plus measurements with the bilogical antenna in both horizontal and vertical positions, first facing the proposed alignment, and then in the direction that exhibited the maximum signal strength in each measurement band.

The magnetic field measurements characterized the prevailing background magnetic field levels, as well as the temporal variations caused by the passing of trains on the existing right-of-way. Measurements were made at two positions at each site, separated by approximately 30 feet. The magnetic field measurements were performed using a pair of three-axis 5 gauss Bartington fluxgate sensors (bandwidth DC to 3 kHz), connected to a National Instruments data acquisition system. Magnetic field waveforms were recorded so that DC and full frequency information is available over the entire sensor bandwidth.

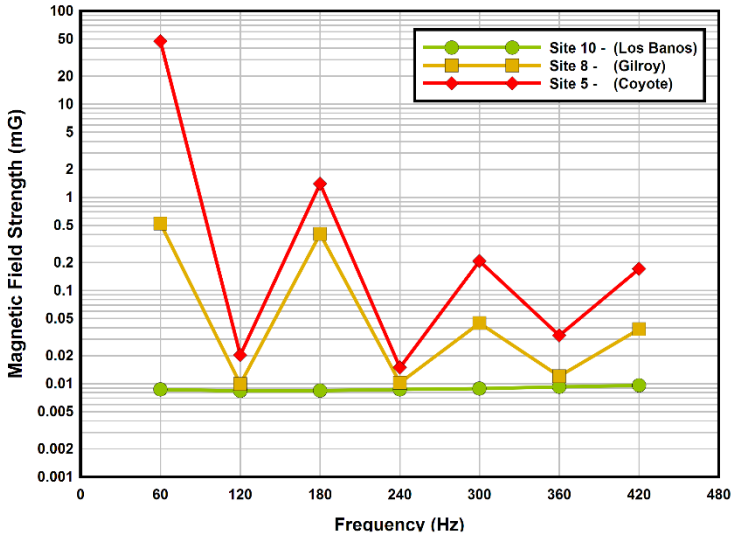
Overview of the Measurement Results

Magnetic Fields

The measured DC magnetic field strengths ranged from 388 milligauss (mG) to 488 mG across the 10 measurement sites. At individual sites, the difference in DC field strength between the two sensors ranged from 15 to 46 mG. These differentials typically are the result of the influence from passing vehicles or nearby steel objects.

AC magnetic field strengths at the 10 sites varied over a range of more than three orders of magnitude, from 0.009 mG to 47 mG. The levels depend almost entirely on a site's proximity to power lines (medium-voltage distribution and high-voltage transmission lines) and other electrical system infrastructure. Such a wide range in observed magnetic field strengths is expected, given the variable levels of development along the project extent.

Figure 1 provides an illustration of the measured AC magnetic field strengths for three representative measurement sites: rural (Los Banos, Site 10), suburban (Gilroy, Site 8), and in close proximity to high-voltage transmission lines (Coyote, Site 5). These sites encompass the full range of observed 60 hertz (Hz) magnetic field levels, with Site 10 the lowest, Site 5 the highest, and Site 6 representing the median level. Levels are plotted for the 60 Hz fundamental.



JANUARY 2019

Figure 1 Average Measured AC Magnetic Field Strengths

Electric Fields

Because of the very broad range of frequencies of interest, the electric field measurements at each site were divided into eight overlapping frequency bands to provide adequate frequency resolution in each band. Table 1 summarizes the maximum magnitude of the measured electric field values by frequency band for each site. The maximum electric fields strengths in bands B0 through B4 varied considerably across sites. Except for band B2 (the AM broadcast band), levels spanned a 30 decibel (dB) range. Even greater variation was seen at higher frequencies (bands B5 through B7), reflecting stronger differences in spectrum usage along the project alignment. Measured maximum levels in these bands varied by up to 45 dB. Variations of this magnitude are not unexpected when encompassing the range of urban, suburban, and rural settings found in the project extent.

10 –Los Banos (rural)	148.4	131.3	134.7	112.3	107.4	83.9	80.4	69.8

Field strength values are in decibel (dB), referenced to 1 microvolt meter/MHz.
GHz = gigahertz
KHz = kilohertz
MHz = megahertz

Figure 2 graphically shows the maximum measured electric field strengths by frequency band for the 10 measurement sites. Typical spectrum uses in each frequency band are also indicated in Figure A3.5-2. Increasing distance from the plot origin indicates higher field strength. Figure 3 shows the variance in RF field strengths across the measurement sites by frequency band. Standard deviations ranged from 4.5 dB in band B2 to as great as 17 dB in band B7.

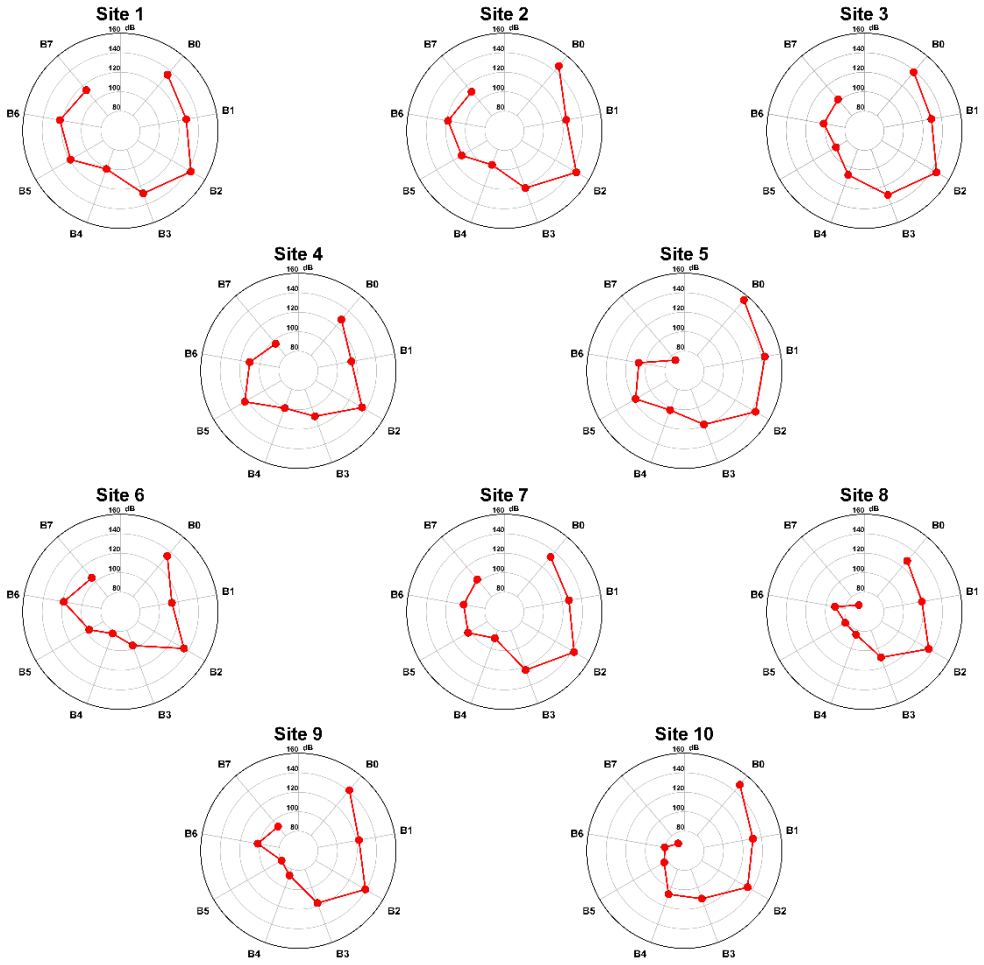
The 10 panels in Figure A3.5-4 graphically show the tabulated electric field strength values from Table A3.5-1.



JANUARY 2019

Figure 4 Maximum Measured Electric Field Strengths

Individual Site Observations

The following discussion very briefly summarizes the EMF measurements conducted at each site. Complete measurement results are plotted and tabulated in the following section.

Site 1 (Newhall Street / Newhall Drive)

This measurement site was near Avaya Stadium. DC magnetic fields were quiet at this location. AC magnetic fields were due to overhead distribution lines. Magnetic fields show some variation due to varying load currents on the power lines, including a step change near the middle.

Site 2 (Montgomery Street / Otterson Street)

This location was South of Diridon Station adjacent to the Pacific Gas and Electric Company (PG&E) Distribution Substation. DC magnetic fields were relatively constant with very small variations. The first sensor had a total magnitude comparable to expected ambient, but the second was lower, indicating influence from nearby steel objects. Multiple trains moved along the alignment, but on the opposite side of the substation, they were sufficiently distant for the DC fluctuations to be quite small. AC magnetic fields in the 10-20 mG range are produced by the substation bus conductors and the power lines connected to the substation.

Site 3 (Communications Hill Boulevard / Curtner Avenue)

Measurements were made near Communications Hill, in a park adjacent to the project extent alignment. Both DC and AC magnetic fields were relatively quiet. DC magnetic fields were comparable in magnitude to the expected geomagnetic ambient level, with a few small variations due to pedestrians in the park passing very near the sensors (e.g., cell phones, strollers). There were no nearby power lines or underground circuits.

Site 4 (Great Oaks Parkway / Las Colinas Road)

This measurement site is immediately adjacent to tracks along Great Oak Parkway. DC magnetic field magnitudes were at expected ambient levels, with many small variations due to passing vehicles on Great Oak Parkway. AC magnetic fields were from overhead distribution lines on the opposite site of the tracks.

Site 5 (Metcalf Road / Coyote Ranch Road)

Measurements were made in front of PG&E Station. Spikes in DC magnetic fields were from passing vehicles along the adjacent road. AC fields were predominantly from the overhead transmission lines—four circuits on two sets of steel lattice towers—with magnitudes of nearly 50 mG at both sensors.

Site 6 (Railroad Avenue / Barrett Avenue)

This measurement site is in Morgan Hill, along Railroad Avenue, across from tracks. The DC magnetic fields were relatively constant with a few spikes due to passing vehicles. AC magnetic fields were less than 1 mG, with overhead distribution lines on the opposite side of the street along the tracks.

Site 7 (Monterey Highway / Las Animas Avenue)

This measurement site is in Gilroy on a cul-de-sac off Las Animas Avenue. This is a quiet area with constant DC magnetic fields and very low AC fields. Adjacent fields are used for livestock grazing. An overhead distribution line runs along the tracks.

Site 8 (State Route 152 / Casa de Fruta Parkway)

This measurement site is on Casa de Fruta Parkway, adjacent to State Route (SR) 152. This is a quiet area with virtually no DC magnetic field variations and essentially zero AC magnetic fields. There were no nearby AC power lines or sources.

Site 9 (Santa Nella Avenue / Fahey Road)

This measurement site is an agricultural area along Santa Nella Road. There were small DC field variations due to vehicles on SR 33. AC fields were in the 1-2 mG range due to distribution lines. AC fields showed variation over time.

Site 10 (Henry Miller Road / Carlucci Road)

Measurements were taken in an agricultural area northeast of Los Banos along Henry Miller Road. DC magnetic field spikes were due to passing trucks. AC fields were quite low. There was a distribution line to the south side of the sensor positions. A shift of the AC fields occurred for several minutes followed by a quick transient, most likely due to a load change on the distribution line such as running of pumps for irrigation.

Site Photographs and Measurement Data

The remainder of this appendix contains photographs and measurement results from each site.

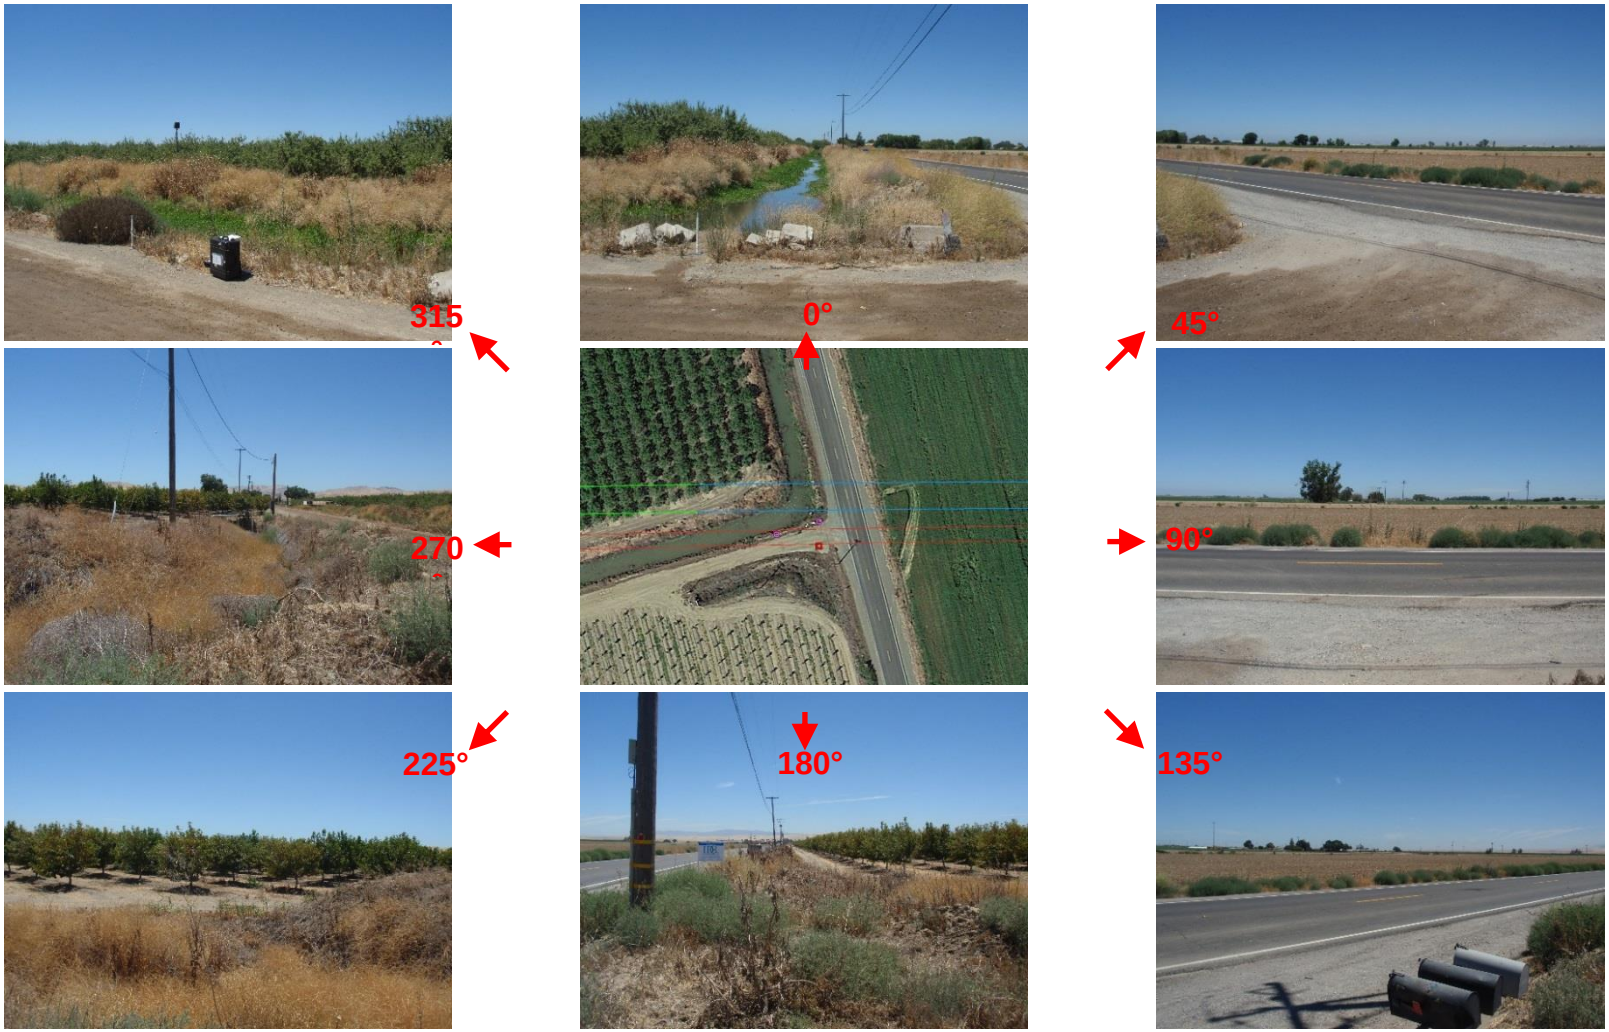
Rural setting with no visible RF sources (Lat 37.126085°, Lon -121.015302°)



JANUARY 2019

Figure 13(b) Location 9: Measurement Location and Site Views

Photos depicting the site from the perspective of the RF measurement location. In the center is a satellite view, indicating the alignment (green line) and measurement points (red = RF, magenta = magnetometers). The satellite view is rotated so that the image at 0° faces the alignment.

JANUARY 2019

Figure 13(c) Location 9: Local EMF Sources

Nearby emitters include distribution lines perpendicular and parallel to the alignment.

Photos depict visible close-proximity emitters. Other emissions sources may exist, but are not visible from the site.

APPENDIX 3.6-A: PUBLIC UTILITIES AND ENERGY FACILITIES

APPENDIX 3.6-A: PUBLIC UTILITIES AND ENERGY FACILITIES

Since publication of the Draft Environmental Impact Report/Environmental Impact Statement, the following substantive changes have been made to this appendix:

- This appendix was updated to reflect missing major utility lines within the public utilities resource study area and to reflect the relocation of the Diana Well under Alternatives 2 and 4.

Table 1a Existing Major Utilities and Energy Facilities within the Public Utilities Resource Study Area under Alternative 1

Utility Type	Provider (Owner)	Stationing	Longitudinal/ Transverse/ Above[1]	Existing Roadway Crossing	Disposition

PG&E = Pacific Gas & Electric Company
CCID = Central California Irrigation District
[1] Longitudinal is defined as a facility located parallel to and within the proposed HSR right-of-way. A transverse facility is one that passes from one side of the proposed HSR right-of-way to the other side of the right-of-way. The designation of "Above" is used for transmission towers that extend above the HSR alignment.

PG&E = Pacific Gas & Electric Company
CCID = Central California Irrigation District
[1] Longitudinal is defined as a facility located parallel to and within the proposed HSR right-of-way. A transverse facility is one that passes from one side of the proposed HSR right-of-way to the other side of the right-of-way. The designation of "Above" is used for transmission towers that extend above the HSR alignment.

n/a = not applicable
PG&E = Pacific Gas & Electric Company
CCID = Central California Irrigation District
[1] Longitudinal is defined as a facility located parallel to and within the proposed HSR right-of-way. A transverse facility is one that passes from one side of the proposed HSR right-of-way to the other side of the right-of-way. The designation of "Above" is used for transmission towers that extend above the HSR alignment.

[1] Longitudinal is defined as a facility located parallel to and within the proposed HSR right-of-way. A transverse facility is one that passes from one side of the proposed HSR right-of-way to the other side of the right-of-way. The designation of "Above" is used for transmission towers that extend above the HSR alignment.

APPENDIX 3.6-B: EXISTING PLUS PROJECT CONDITIONS ENERGY ANALYSIS

METHODOLOGY

Per California Environmental Quality Act (CEQA) requirements, an environmental impact report (EIR) must include a description of the existing physical environmental conditions in the vicinity of the project. Those conditions, in turn, "will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant" (CEQA Guidelines Cal. Code Regs., tit. 14, § 15125(a)).

For a project such as the high-speed rail (HSR) project that would not commence operation for almost 10 years and would not reach full operation for almost 25 years, use of only existing conditions as a baseline for energy impacts would be misleading. It is more likely that existing background traffic volumes (and background roadway changes from other programmed traffic improvement projects) and vehicle emission factors would change between today and 2040 than it is that existing conditions would remain unchanged over the next 25 years. For example, regional transportation plans (RTP) include funded transportation projects that are programmed to be constructed by 2040. To ignore that these projects would be in place before the HSR project reaches maturity (i.e., the year at which HSR-related traffic emissions reach their maximum) and to evaluate the HSR project's energy impacts ignoring that these RTP improvements would change the underlying background conditions to which HSR project traffic would be added, would be misleading because it would represent a hypothetical comparison.

Therefore, the energy analysis uses a dual baseline approach. That is, the HSR system's energy impacts are evaluated both against existing conditions and against background (i.e., No Project) conditions as they are expected to be in 2040. This approach complies with CEQA (see Woodwark Park Homeowners Assn v. City of Fresno (2007), 150 Cal.App.4th 683, 707 and Sunnyvale West Neighborhood Assn. v. City of Sunnyvale (2010), 190 Cal.App.4th 1351). Results for both baselines are presented. The results comparing the project with the future expected baseline are presented in detail in the main text of the Appendix 3.6-D, Energy Analysis Memorandum. The results comparing the project with existing conditions are presented in the main text in summary format; details are presented in this attachment. This analysis informs the public of potential project impacts under both baselines, but focuses the analysis on the baseline analysis more likely to occur.

Using the methodologies described in the Appendix 3.6, the impacts of the proposed project have been evaluated and are discussed in the following sections.

Electrical Requirements of the HSR

The electrical demand for the propulsion of the trains, the operation of the trains at terminal stations, and in storage depots and maintenance facilities etc., has been conservatively estimated by the project's engineers. As shown in Table 1, this electrical demand is equivalent to an increase in energy use of approximately 172,495 million British thermal units (MMBtu) per year for the medium ridership scenario and 189,745 MMBtu per year for the high ridership scenario for all alternatives. This change is predicted to occur in both the Existing Plus Project conditions and the 2040 Plus Project conditions.

Table 1 Power Plant Energy Changes due to the Project

Scenario	Change in Energy due to HSR (MMBtu/year)
Medium Ridership	172,495
High Ridership	189,745

Source: HNTB 2017; Authority 2017
GWh = gigawatt hour
HSR = high-speed rail
MMBtu = million British thermal units

The HSR system's electrical requirements would be met through the state's electrical grid, and no one generation source for the electrical power requirements can be positively identified. Energy changes from power generation can therefore be predicted on a statewide level only.

On-Road Vehicle Travel

Estimated vehicle miles traveled (VMT) for the Existing and Existing Plus Project conditions are provided in Table 2. These values, together with associated average daily speed estimates, were developed on a county-by-county basis and then summed for the state as a whole. As shown, the HSR is predicted to reduce roadway VMT by over 3.4 billion miles annually statewide due to travelers choosing to use the HSR rather than drive for the medium ridership scenario, resulting in an energy reduction of 15.6 million MMBtu per year. Under the high ridership scenario, HSR would reduce roadway VMT by over 4.7 billion miles annually statewide, resulting in an energy reduction of 21 million MMBtu per year.

VMT = vehicle miles traveled
HSR = high-speed rail
MMBtu = million British thermal units

Aircraft Travel

As shown in Table 3, the number of plane flights statewide is anticipated to decrease with the HSR due to travelers choosing to use the HSR rather than fly to their destination. An average fuel consumption rate was calculated for the aircraft based on the profile of aircraft currently servicing the San Francisco to Los Angeles corridor. The number of air trips removed due to the HSR was estimated using the travel demand modeling analysis conducted for the project. As shown in Table 3, the Existing Plus Project condition is estimated to reduce the number of statewide air trips by over 80,000 trips statewide, resulting in an energy reduction of approximately 9.6 million MMBtu per year for the medium ridership scenario and 9.2 million MMBtu per year for the high ridership scenario, as compared to the existing conditions.

Table 3 Aircraft Energy Changes due to HSR (2015)

Origin	Number of Flights Removed	Change in Energy due to HSR (MMBtu/Year)
Medium Ridership Scenario		
San Francisco Bay Area	-31,662	-3,798,621.8
Statewide Total	-80,137	-9,614,376.6
High Ridership Scenario		
San Francisco Bay Area	-30,303	-3,635,622.1
Statewide Total	-77,100	-9,250,003.0

Source: Authority 2017
MMBtu = million British thermal units

SUMMARY OF RESULTS

As, shown in Table 4, for the medium ridership scenario, the existing plus project scenario is estimated to reduce roadway energy by approximately 2 million MMBtu per year, reduce energy due to plane travel by approximately 3.8 million MMBtu per year, and increase electrical energy demand by approximately 172,495 MMBtu per year, resulting in an overall regional energy savings of approximately 5.7 million MMBtu per year over existing conditions. For the high ridership scenario, the Existing Plus Project conditions are estimated to reduce roadway energy by approximately 2.8 million MMBtu per year, reduce energy due to plane travel by approximately 3.6 million MMBtu per year, and increase electrical energy demand by approximately 189,745 MMBtu per year, resulting in an overall regional energy savings of approximately 6.2 million MMBtu per year over existing conditions.

The analysis conducted for the project estimated the changes in regional energy use anticipated with and without the HSR. The analysis estimated the energy changes from reduced on-road VMT, reduced intrastate plane travel, and increased electrical demand. Although the HSR system would result in an increase in electricity demand, it is predicted to reduce the energy demands from automobile and plane travel, resulting in an overall beneficial effect on statewide energy use.

Table 4 Estimated Regional Energy Changes due to Existing Plus Project compared to Existing Conditions (2015)

Project Element	Change in Energy due to HSR (MMBtu/Year)	
	Medium Ridership Scenario	High Ridership Scenario

APPENDIX 3.6-C: WATER USE ASSESSMENT

APPENDIX 3.6-C WATER USE ASSESSMENT

This appendix presents an analysis and evaluation of anticipated water use requirements for both construction and operation of the California High-Speed Rail (HSR) System for the San Jose to Central Valley Wye Project Extent (project). This appendix also identifies current water use (most of which is agricultural) within the project footprints, and available water supply sources to meet the anticipated HSR water demand for construction.

Executive Summary

The project alternatives share termini at Scott Boulevard on the north and Henry Miller Road/Carlucci Road on the east. The alignments would cross urban and rural areas in unincorporated Santa Clara, San Benito, and Merced Counties. Volume 3 of the environmental impact report (EIR)/environmental impact statement (EIS) provides detailed design drawings that support the descriptions of the alternatives.

The project would be grade-separated, meaning that the HSR would cross roads, railroads, and other transport facilities using overpasses or underpasses, allowing it to operate independently of other modes of transportation. HSR rights-of-way would be fenced and access controlled to prohibit public or vehicle access. The project footprint for each alternative would consist of the permanent HSR right-of-way, station, and maintenance facility areas. Grade separations and traction power electrical facilities would require additional right-of-way.

Analysts estimated water demand for construction and operation of the project alternatives. Analysts then evaluated existing water use along each project alternative and compared the existing water use to the estimated demand for construction and operation of the alternatives. Existing water consumption was estimated based on the current land uses within the project footprint and a water consumption factor for each type of land use. This comparison indicated that construction and operation of the project alternatives would result in a net decrease in annual water consumption compared to the current use of the land. Construction demand for water would be an estimated 10 percent of the existing annual water use of the land within the right-of-way for Alternative 1, 9 percent for Alternative 2, 10 percent for Alternative 3, and 9 percent for Alternative 4.

The alternatives include HSR stations at San Jose and downtown Gilroy or east Gilroy, a maintenance of way facility (MOWF) south or east of Gilroy and a maintenance of way siding (MOWS) near Turner Island Road. Therefore there would be project-related demand for water for station and maintenance facility operations in addition to water demand for construction of the alignment, stations, and maintenance facilities. A portion of the land that would be permanently utilized for construction of the alignment in areas of Santa Clara, San Benito, and Merced Counties is currently in agricultural use and construction of the alternatives would permanently remove land from agricultural production. Additionally, temporary construction easements (TCE) would be required to support construction activities and would generally be located adjacent to active construction areas, temporarily removing additional agricultural lands from production. Once construction of the project is completed, agricultural lands affected by TCEs would be returned to agricultural use.

Background

The California High-Speed Rail Authority (Authority), a state governing board formed in 1996, has responsibility for planning, designing, constructing, and operating the California HSR System. Its mandate is to develop an HSR system that coordinates with the state's existing transportation network, which includes intercity rail and bus lines, regional commuter rail lines, urban rail and bus transit lines, highways, and airports. The California HSR System would provide intercity, high-speed service on more than 800 miles of tracks throughout California connecting the major population centers of Sacramento, the San Francisco Bay Area, the Central Valley, Los Angeles,

the Inland Empire, Orange County, and San Diego. The California HSR System would be implemented in two phases. Phase 1 would connect San Francisco to Los Angeles and Anaheim via the Pacheco Pass and the Central Valley. The sequence of system phasing would first connect the Silicon Valley to the San Joaquin Valley for initial operating section service in 2025. The San Jose to Merced Project Section (of which the San Jose to Central Valley Wye Project Extent is a part) would connect the San Francisco to San Jose Project Section on the north to the Merced to Fresno Project Section on the east. The project runs through portions of Santa Clara, San Benito, and Merced Counties. The project is divided into five subsections: San Jose Diridon Station Approach, which begins at Scott Boulevard; Monterey Corridor; Morgan Hill and Gilroy; Pacheco Pass; and San Joaquin Valley (which ends at Carlucci Road in an unincorporated area of Merced County).

Methodology

Analysts completed the following steps to estimate potential water needs required under the project alternatives and available water supplies:

1. Reviewed existing relevant information, reports, and documents to identify project features and activities that would require significant water usage during construction and operation.
2. Identified the expected land requirements (acreage) and land uses that would be permanently converted from use for construction of right-of-way, stations, and maintenance facilities for each alternative.
3. Developed water demand estimates for construction of the alignment, stations, and maintenance facilities for each alternative.
4. Developed water demand estimates for operation of stations and maintenance facilities.
5. Calculated the existing water use of the land for construction of the alternatives. Water use factors (acre-feet of water used per acre of land per year) were applied to each land use except for agricultural use; county-specific water use rates were developed from recent county-specific data and were applied to the amount of agricultural land for each county.
6. Identified available existing water supply and additional water supply sources, if needed, to provide the required water to each section feature, during both construction and operation.

The following subsections provide a more detailed description of the approach for each step.

Identification of Project Features with Significant Water Usage

During construction, water would be required for construction activities including preparation of cement, concrete work, earthwork and soil conditioning, fugitive dust suppression, landscaping, and operation of tunnel boring machines (TBM). Operation would require water for operation of stations and maintenance facilities. Radio towers, traction power substations, and switching and paralleling stations would be unmanned, remotely operated facilities with no dedicated water supply and no water use requirements. Water use factors and estimated existing water demand for permanently converted land for each alternative is summarized in Table 1.

Estimating Future Water Demand Requirement for the Project

Water demand estimates were developed for construction activities and for operations including two stations (San Jose Diridon Station and Downtown Gilroy or East Gilroy Station), one LMF/MOIF near Gilroy (South Gilroy or East Gilroy LMF/MOIF), and one MOWS near Turner Island Road. The process for estimating water demand for construction of each alternative included the following:

- Identification of the project footprint for each of the three project alternatives
- Identification of the different construction components associated with construction of the track, including:
  - Manufacturing concrete
  - Earthwork and soil conditioning
  - Dust suppression
  - Landscaping
  - TBM operation

Analysts developed water usage estimates for construction of the track, stations, maintenance facilities, and tunnels based on the anticipated project construction schedule.

Water Use Assessment

Existing Water Use and Water Supply Sources

Analysts evaluated existing land use information for each project alternative based on city and county general plan land use data. The predominant land use for each project alternative is agricultural (ranging from 37 percent to 46 percent) and parks, recreational, and open space (ranging from 46 percent to 48 percent). Other land uses are categorized as residential, commercial, industrial, public facilities, and transportation land for the purposes of this analysis. The land use factors to determine existing water use for land currently in residential, commercial, public facilities, parks, recreational, and open space, and transportation land uses are the same factors utilized in the Fresno Urban Water Management Plan (City of Fresno 2008). Analysts obtained water use for agricultural land in Santa Clara, San Benito, and Merced Counties from the California Department of Water Resources (California Department of Water Resources) (DWR 2005, 2006, 2007, 2008, 2009, 2010, 2017).

To determine water use for the agricultural areas, analysts obtained applied water rates (acre-feet of water per acre of land) and irrigated acres for each crop type were obtained from the DWR database (DWR 2017). Data tables were available for calendar years 1998 through 2010. In the table, water use varies from less than 1 acre-foot per acre per year for grain to 5.6 acre-feet per acre per year for rice. Acre-feet per acre per year for each crop type and the number of irrigated acres for each crop type for calendar years 2005 through 2010 were averaged to calculate the average acre-feet per acre per year for Santa Clara, San Benito, and Merced Counties. Analysts calculated the average water rate for all crops in these three counties for calendar years 2005 to 2010 as:

Acre-foot of water

An acre-foot of water is the volume equal to a sheet of water 1 acre in area and 1 foot in depth.

- Santa Clara County—2.8 acre-feet per acre per year
- San Benito County—1.9 acre-feet per acre per year
- Merced County—3.7 acre-feet per acre per year

Analysts applied the most recent available DWR water use data to the agricultural area for each county for each alternative. The rates then were used to calculate existing water use for the project footprint of each alternative in each county. The resulting existing water use for each alternative is shown in Table 1.

[1] Acres of land use are calculated based on the permanent right-of-way for track alignment, stations, and maintenance facilities for each alternative.

The Santa Clara Valley Water District supplies water to all of Santa Clara County. Water demand in 2015 was 260,000 acre-feet per year. Water demand in 2040 is projected to be 435,100 acre-feet per year. Water is distributed in incorporated areas of Santa Clara County by the San Jose Water Company, San Jose Municipal Water System, City of Morgan Hill Water Division, and City of Gilroy Public Works. Local sources include natural groundwater recharge and surface water

supplies, including surface water rights held by the Santa Clara Valley Water District and the San Jose Water Company, and also use of recycled water within Santa Clara County. Residential water use is the primary water use in Santa Clara County. Many residents in rural and unincorporated areas of Santa Clara County rely on private groundwater wells for drinking water (SCVWD 2015).

The San Benito County Water District provides water to primarily agricultural customers in unincorporated areas of San Benito County. In 2015 the U.S. Department of the Interior, Bureau of Reclamation water allocation to the San Benito County Water District was 43,800 acre-feet of which 8,250 acre-feet was designated for municipal and industrial uses and 35,550 was designated for agricultural uses (County of San Benito 2016a).

Water is provided in unincorporated areas of Merced County by public water suppliers that obtain their water primarily from the Central Valley Project operated by U.S. Department of the Interior, Bureau of Reclamation, the California Aqueduct operated by the DWR, or from private groundwater wells that are also a major water supply source in unincorporated areas of Merced County. Consistent with the agricultural nature of Merced County, water is used primarily for agriculture in the Pacheco Pass and San Joaquin Valley Subsections. The water suppliers and acreage that each supplier covers in western Merced County are:

- San Luis/Delta-Mendota Water Authority—1,100,000 acres
- Henry Miller Reclamation District/San Luis Canal Company—45,000 acres
- Grassland Water District—51,537 acres
- Central California Irrigation District—143,000 acres
- Del Puerto Water District-- 52,800 acres (9,000 acres in Merced County)

The project alternatives are located in or near the service areas of these suppliers, which rely predominantly on surface water, as they extend through western Merced County. In addition, groundwater could be used for some construction-related activities. According to the U.S. Geological Survey (USGS) California Water Sciences Center, while surface water for agriculture is used when it is available (via the Central Valley Project), the San Joaquin Basin also relies heavily on groundwater. USGS estimates that groundwater accounts for approximately 33 percent of the annual supply of water used for both agricultural and urban purposes in the basin (USGS 2016). Existing agricultural water use for irrigation in Merced County was 1,374 million gallons per day (mgd) (1.5 million acre-feet per year) in 2010, including 981 mgd (1.1 million acre-feet per year) of surface water (71 percent) and 393 mgd (0.4 million acre-feet per year) of groundwater (29 percent) (USGS 2017). Existing groundwater use within the project footprint for irrigation in Merced County is estimated at 918 acre-feet per year for all project alternatives.

Annual water use for construction for each alternative is summarized in Table 2. Annual water use for construction would be approximately 868 acre-feet per year for Alternative 1, 842 acre-feet per year for Alternative 2, 912 acre-feet per year for Alternative 3, and 887 acre-feet for Alternative 4. These values represent between 9 and 10 percent of the current water usage.

Construction Water Use

The amount of water that would be used during construction was estimated for preparation of concrete, operation of TBMs, and concrete work, earthwork, dust control, and irrigation for reseeding and landscaping for the track alignments (Table 2).

Table 2 Concrete, Tunnel Boring, and Construction Water Use by Alternative and Activity

Length of Construction	Construction Activity	Water Use	
		Annual Construction Use (acre-feet/year)	Total 5-Year Construction Use Acre-Feet
Alternative 1			
89.6 miles	Concrete Batch Plants (Pacheco Tunnel)	17	83
	Concrete batch plants (Project Section)	57	285
	Tunnel boring[2]	366	1,829
	Construction water use[3]	428	2,141
	Total	**868**	**4,339**

	Construction water use[3]	453	2,261
	Total	**887**	**4,426**

Source: Authority 2017a; 2017b, 2017c HNTB 2018a

[1] Annualized water use is based on a total of 784 working days of tunnel boring machine operation.

[2] Construction water use includes water used for on-site concrete work, earthwork, dust control, and landscaping.

Analysts used industry construction standards to estimate the amount of concrete needed to construct track alignments and associated viaducts and bridges. These quantities were used to estimate the amount of concrete required for construction of elevated, at-grade, retained fill, and below-grade sections of track, bridges, and other structures required for each project alternative (HNTB 2018a). Analysts estimated the water needed for preparation of concrete at 31 gallons per cubic yard of concrete, and estimated the water use for construction including concrete work, earthwork, dust control, and irrigation based on the number of water trucks included in the on-site vehicle construction schedule for each project alternative.

Table 3 provides a comparison of annual existing water use and construction water use for the project alternatives. As shown, construction of any one of the project alternatives would result in a net decrease in annual water use for that portion of the project. Current annual water use is therefore greater than the annual water use would be required for project construction.

It is noted that construction water use is not continuous, because needs are sporadic and a function of the particular construction activities at the time. Water would be supplied to construction work sites by water tanker truck or by temporary pipeline. As a result, construction demand is frequently offset by a water supply system storage, so there would not be a noticeable drop in public utility water pressure or flow during construction-related activities. Also, the construction contractors could provide water storage on-site, and replacement water can be planned for periods of low demand. These activities would reduce potential surges in water demand to utility customers.

Table 3 Annual Construction Water Use Summary by Alternative

County	Annual Water Use (acre-feet per year)		
	Existing Use	Construction Use	Percent of Existing Use
Alternative 1			
Santa Clara County	4,043	494	12
San Benito County	1,729	22	1
Merced County	2,931	351	12
Total	**8,703**	**868**	**10**

Operations Water Use

Water would also be required for operation of stations and maintenance facilities for the project alternatives. The San Jose Diridon Station would include restroom facilities and drinking water fountains. The estimated average potable water demand for the San Jose Diridon Station would be 24,200 gallons per day (gpd). Approximately two-thirds of this water use (16,025 gpd) would be anticipated for use within the station, while the remaining third (8,650 gpd) would be for outdoor use. Water consumption for operation of the Downtown Gilroy Station would be approximately 15,800 gpd based on the estimated station and grounds square footages. The East Gilroy Station would use approximately 15,350 gpd; an estimated 10.500 gpd would be used within the Downtown Gilroy station and 5,330 gpd would be used for outdoor use. For the East Gilroy Station approximately 10,200 gpd potable water would be used within the station and the remaining 5,200 gpd would be used outdoors. The total water consumption for both the San Jose Diridon Station and the Downtown Gilroy Station would be 40,000 gpd, and for the San Jose Diridon Station and the East Gilroy Station water consumption would be 39,500 gpd. Approximately two-thirds of the water for operation of the two stations would be potable water consumption.

Water consumption for operation of the MOWF and the MOWS would be required for personnel, including operation of drinking fountains, restrooms, kitchen/canteens, showers, and other potable uses. Potable water consumption would be approximately 84,000 gpd at the MOWF and 98,000 gpd at the MOWS, for a total of 182,000 gpd of potable water for both maintenance facilities. Water consumption would also be required for the MOWF and the MOWS for use by road and rail-mounted equipment including rail-grinding train runs and other maintenance activities. Water used for maintenance activities at the MOWF and the MOWS would not need to be of drinking water quality. Nonpotable water use is estimated as 1,000 gpd for operation of the MOWF and 1,000 gpd for operation of the MOWS (Authority 2017b, 2017c). Annual total water consumption for operation of the MOWF and the MOWS for potable and industrial uses would be 184,000 gpd, of which 182,000 gpd would be for potable uses and 2,000 gpd would be for nonpotable uses.

Conclusions

Construction of the project alternatives would result in net decrease in annual water consumption relative to existing water consumption within the project footprints. The decrease would be greatest under Alternative 2 (requiring 9 percent of existing use for construction), followed by Alternative 1 (requiring 10 percent of existing use), Alternative 3 (requiring 10 percent), and Alternative 4 (requiring 10 percent), as summarized in Table 3. Between 38 percent and 46 percent of the land that would be utilized for construction of the project alternatives is currently in

agricultural use. Per-acre water demand for agricultural land in Merced County was estimated at 3.7 acre-feet per year per acre of agricultural land, for San Benito County 1.9 acre-feet per year per acre, and for Santa Clara County 2.8 acre-feet per year per acre. Construction of the project would permanently remove the land from agricultural production, resulting in a reduction in water use for the converted land. Additionally, TCEs would be required to support construction activities along the project and would generally be located adjacent to active construction areas. These TCEs would temporarily remove additional agricultural lands from production, also resulting in a further temporary reduction in water consumption during the construction period. It is assumed that once construction of the project is completed, those agricultural lands affected by TCEs would be returned to agricultural use.

Water consumption for operation of the two stations would be approximately 40,000 gpd and for operation of the maintenance facilities in the project would be approximately 184,000 gpd for a total of 224,000 gpd (250 acre-feet per year). This is approximately 2.9 percent of existing water use for Alternative 1, 2.6 percent of existing water use for Alternative 2, 2.8 percent of existing water use for Alternative 3, and 2.8 percent of existing water use for Alternative 4. Construction and operation of the project would therefore reduce water consumption for all project alternatives.

APPENDIX 3.6-D: ENERGY ANALYSIS MEMORANDUM

Memorandum

DATE: Issued: November 16, 2016
Rev.#1: November 23, 2017
Rev.#2: March 27, 2017

TO: Authority and Regional Consultant Environmental Staff

FROM: Alice Lovegrove and Eddie Tadross, WSP Parsons Brinckerhoff

CC: Lisa Nungesser and Bryan Porter

SUBJECT: California High-Speed Rail Statewide Criteria Pollutant, GHG and Energy Analysis

---

This revised version of the memo includes a discussion of statewide energy consumption for on-road vehicles, aircraft, and electrical energy that would change with future operation of the project. In addition, the statewide Excel spreadsheet summaries that accompany this memo have also been updated. Should you have any questions, please contact Alice Lovegrove at Lovegrove@pbworld.com or Eddie Tadross at Tadross@pbworld.com.

Overview

This memo describes the calculation of statewide criteria pollutant and greenhouse gas (GHG) emission levels associated with future operation of the California High-Speed Rail Project. This memo is meant to accompany Excel spreadsheet files with statewide summary emission data for the following high-speed rail (HSR) sections: San Francisco to San Jose, San Jose to Merced, Bakersfield to Palmdale, Palmdale to Burbank, Burbank to Los Angeles, and Los Angeles to Anaheim. An earlier analysis of emission levels for the Merced to Fresno and Fresno to Bakersfield HSR sections was completed several years ago.

The spreadsheets consist of multiple tables. The list below explains what is included as part of each spreadsheet file.

- MED - EX(2015) & EX+PROJ = Medium Alternative 2015 (Existing & Existing Plus Project)
- MED - 2029 NB&BD = Medium Alternative 2029 (No Build & Build)
- MED - 2040 NB&BD = Medium Alternative 2040 (No Build & Build)
- MED EXT - EX(2015) & EX+PROJ = Medium Extended Alternative 2015 (Existing & Existing Plus Project)
- MED EXT - 2029 NB&BD = Medium Extended Alternative 2029 (No Build & Build)
- MED EXT - 2040 NB&BD = Medium Extended Alternative 2040 (No Build & Build)
- HIGH - EX(2015) & EX+PROJ = High Alternative 2015 (Existing & Existing Plus Project)
- HIGH - 2029 NB&BD = High Alternative 2029 (No Build & Build)
- HIGH - 2040 NB&BD = High Alternative 2040 (No Build & Build)

Provided below is a description of the emission calculations. You can also use this text in preparing the air quality section for your HSR section environmental impact report/environmental impact statement (EIR/EIS).

Statewide and Regional Operational Emissions Calculations

The emission burden analysis of a project determines a project's overall impact on air quality levels. The project section would affect long-distance, city-to-city travel along freeways and highways throughout the state, as well as long-distance, city-to-city aircraft takeoffs and landings. The HSR system would also affect electrical demand throughout the state. Analysts calculated criteria pollutant and GHG operational emissions for three ridership scenarios: a medium ridership scenario of the Silicon Valley to Central Valley line (from San Jose to North of Bakersfield), a medium ridership scenario of an extended Silicon Valley to Central Valley line (from San Francisco to Bakersfield), and a high ridership scenario of the Silicon Valley to Central Valley line for Existing (2015) and Phase 1 of Statewide High-Speed Rail Build Out (2040) years. All applicable scenarios are based on the level of ridership as presented in the Authority's *2016 Business Plan* (Authority 2016). The tables in the effects analysis therefore present three values for operational emissions for each pollutant, corresponding to these three scenarios.

On-Road Vehicles

Analysts evaluated on-road vehicle emissions using average daily VMT estimates and associated average daily speed estimates for each affected county. Analysts estimated emission factors using the emission factors using the California Air Resources Board (CARB) emission factor program, EMission FACtors 2014 (EMFAC2014), which accounts for existing regulations that would reduce emissions, such as the Pavley Clean Car Standards. Parameters were set in the program for each individual county to reflect conditions within each county and statewide parameters to reflect travel through each county. The analysis was conducted for the following modeling years:

- Existing (Year 2015)
- Opening Year (Year 2029)
- Horizon Year (Year 2040)

To determine overall pollutant burdens generated by on-road vehicles, analysts multiplied the estimated VMT by the applicable pollutant's emission factors, which are based on speed, vehicle mix, and analysis year.

Aircraft

Analysts used the Federal Aviation Administration's Aviation Environmental Design Tool (AEDT) to estimate aircraft emissions. This tool estimates the emissions generated from specified numbers of landing and take-off cycles. Along with emissions from the aircraft themselves, emissions generated from associated ground maintenance requirements are included. Analysts calculated average aircraft emissions based on the profile of aircraft currently servicing the San Francisco to Los Angeles corridor. Analysts estimated the number of air trips removed attributable to the HSR using the results of the travel demand modeling analyses conducted for the project section, based on the ridership estimates presented in the California High-Speed Rail Authority's *2016 Business Plan* (Authority 2016).

Power Plants

Analysts conservatively estimated the electrical demands caused by propulsion of the trains and the trains at terminal stations and in storage depots and maintenance facilities as part of the project section design. Analysts derived average emission factors for each kilowatt-hour required from CARB statewide emission inventories of electrical and cogeneration facilities data along with USEPA eGRID2012 (released 10/2015) electrical generation data. The energy estimates used in this analysis for the propulsion of the HSR include the use of regenerative brake power.

The HSR system is currently analyzed as if it would be powered by the state's current electric grid. This is a conservative assumption because of the state requirement that an increasing fraction of electricity (50 percent by 2030) generated for the state's power portfolio come from renewable energy sources. As such, the emissions generated for the HSR system are expected to be lower in the future than the emissions estimated for this analysis. Furthermore, under the 2013 Policy Directive POLI-PLAN-03, the Authority has adopted a goal to purchase 100 percent of the HSR system's power from renewable energy sources.

Greenhouse Gas Analysis

As discussed in Section XX [of the EIR/EIS], Definition of Resource Study Area, the project section would reduce long-distance, city-to-city travel along freeways and highways throughout the state, as well as long-distance, city-to-city aircraft takeoffs and landings. The project section would also affect electricity demand throughout the state. These elements would affect GHG emissions in both the statewide and regional study areas. The methodology for estimating GHG emissions associated with operations of the project section is discussed below.

On-road Vehicle Emissions

Analysts conducted the on-road vehicle GHG emission analysis using the same methods and RSAs as described for air quality emission calculations in Section X, On-Road Vehicles.

Aircraft Emissions

Analysts calculated aircraft emissions by using the fuel consumption factors and emission factors from the CARB's 2000–2014 *Greenhouse Gas Emissions Inventory Technical Support Document* and the accompanying technical support document. The emission factor includes both landing and take-off and cruise operations (formula: aircraft emissions per flight = fuel consumption × emission factor; aircraft emissions = flights removed × aircraft emissions per flight). Analysts calculated average aircraft GHG emissions based on the profile of intrastate aircraft currently servicing the San Francisco to Los Angeles corridor. Analysts estimated the number of air trips removed attributable to the project section through the travel demand modeling analysis conducted for the project section, based on the ridership estimates presented in the Authority's *2016 Business Plan* (Authority 2016).

Power Plant Emissions

The electrical demands due to propulsion of the trains, stations, storage depots and maintenance facilities were calculated as part of the project design. Average GHG emission factors for each kilowatt-hour required were derived from USEPA eGRID2012 electrical generation data. The energy estimates used in this analysis for the propulsion of the HSR include the use of regenerative brake power.

In addition, because of the state requirement that an increasing fraction (50 percent by 2030) of electricity generated for the state's power portfolio come from renewable energy sources, the emissions generated for the HSR system are expected to be lower in the future when compared to emissions estimated for this analysis.

Energy Analysis

As discussed in Section XX [of the EIR/EIS], Definition of Resource Study Area, the project section would reduce long-distance, city-to-city travel along freeways and highways throughout the state, as well as long-distance, city-to-city aircraft takeoffs and landings. The project section would also affect electricity demand throughout the state. These elements would affect energy in both the statewide and regional study areas. The methodology for estimating energy associated with operation of the project section is discussed below.

On-road Vehicle Energy Usage

Analysts conducted the on-road vehicle energy analysis using the same inputs and RSAs as described for air quality emission calculations in Section X, Energy rates were determined through the use of carbon balance equations as recommended by CARB.

Aircraft Energy Usage

Analysts calculated aircraft energy use by using the fuel consumption factors from the CARB's 2000–2014 *Greenhouse Gas Emissions Inventory Technical Support Document* and the accompanying technical support document. The energy use includes both landing and take-off and cruise operations (formula: aircraft energy per flight = fuel consumption × btu/gallon of fuel; aircraft energy = flights removed × aircraft energy per flight). Analysts calculated average aircraft energy based on the profile of intrastate aircraft currently servicing the San Francisco to Los Angeles corridor. Analysts estimated the number of air trips removed attributable to the project section through the travel demand modeling analysis conducted for the project section, based on the ridership estimates presented in the Authority's *2016 Business Plan* (Authority 2016).

Energy Usage

The electrical demands due to propulsion of the trains, stations, storage depots and maintenance facilities were calculated as part of the project design. Analysts estimated the energy use based on the ridership estimates and train operating characteristics as presented in the Authority's *2016 Business Plan* (Authority 2016).

APPENDIX 3.7-A: SPECIAL-STATUS SPECIES SUBJECT TO PROJECT IMPACTS

Since publication of the Draft Environmental Impact Report/Environmental Impact Statement, the following substantive changes have been made to this appendix:

- Table 2 was updated to address the California Fish and Game Commission's designation of the southern California/Central Coast population of mountain lion under the California Endangered Species Act and the monarch butterfly's status as a candidate for listing under the federal Endangered Species Act.

Table 1 Special-Status Plant Species Potentially Subject to Project Impacts

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Alkali milkvetch *Astragalus tener* var. *tener*	–/–/1B.2	Playas, on adobe clay in valley and foothill grassland, vernal pools on alkaline soils; 1-60 meters	Nine CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Bent-flowered fiddleneck *Amsinckia lunaris*	–/–/1B.2	Coastal bluff scrub, valley and foothill grasslands, cismontane woodlands; 3-500 meters	Two CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Big-scale balsamroot *Balsamorhiza macrolepis*	–/–/1B.2	Sometimes on serpentine soils in chaparral, cismontane woodland, valley and foothill grassland; 90-1,555 meters	Six CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Monterey Corridor Subsection.
Brittlescale *Atriplex depressa*	–/–/1B.2	Alkaline clay soils in chenopod scrub, playas, valley and foothill grasslands; 1-320 meters	Two CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
California alkali grass *Puccinellia simplex*	–/–/1B.2	Alkaline, vernally mesic; sinks, flats, and lake margins in chenopod scrub, meadows and seeps, valley and foothill grasslands, and vernal pools; 2-930 meters	Seven CNDDB specific extant occurrence polygons in regional RSA; two overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.
Caper-fruited tropidocarpum *Tropidocarpum capparideum*	–/–/1B.1	Grasslands on alkaline hills; below 455 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for all subsections.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Chaparral ragwort *Senecio aphanactis*	–/–/2B.2	Oak woodland, coastal scrub, chaparral, open sandy or rocky areas, on alkaline soils; 15-800 meters	Three CNDDB specific extant occurrence polygons in regional RSA; two overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass Subsection.
Colusa grass *Neostapfia colusana*	FT/SE/1B.1	Adobe soils of large vernal pools; 5-200 meters	38 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Congdon's tarplant *Centromadia parryi* ssp. *congdonii*	–/–/1B.1	Alkaline soils in annual grassland, on lower slopes, flats, and swales, sometimes on saline soils; below 230 meters	Six CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Jose Diridon Station Approach and Monterey Corridor Subsections.
Coulter's goldfields *Lasthenia glabrata* ssp. *coulteri*	–/–/1B.1	Coastal salt marshes and swamps, grasslands, vernal pools, alkali sinks, playas, in alkaline soils; 1-1,220 meters	Three CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Coyote ceanothus *Ceanothus ferrisiae*	FE/–/1B.1	Serpentine soils in chaparral, coastal scrub, and valley and foothill grassland; 120-460 meters	Seven CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy Subsection.
Delta button-celery *Eryngium racemosum*	–/SE/1B.1	Riparian scrub in seasonally inundated depressions on clay soils; 3-30 meters	18 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Fragrant fritillary *Fritillaria liliacea*	–/–/1B.2	Adobe soils of interior foothills, coastal prairie, coastal scrub, valley and foothill grassland, often on serpentinite; 3-410 meters	14 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Monterey Corridor and Morgan Hill and Gilroy Subsections.
Greene's tuctoria *Tuctoria greenei*	FE/SR/1B.1	Dry vernal pools; 30-1,070 meters	Six CNDDB specific extant occurrence polygons in the regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Hairless popcornflower *Plagiobothrys glaber*	–/–/1A	Alkaline meadows and seeps, coastal salt marsh and swamps; 15-180 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy Subsection.
Hairy Orcutt grass *Orcuttia pilosa*	FE/SE/1B.1	Vernal pools; 46-200 meters	One CNDDB specific extant occurrence polygon in the regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Hall's bush-mallow *Malacothamnus hallii*	–/–/1B.2	Chaparral and coastal scrub; 10-760 meters	28 CNDDB specific extant occurrence polygons in regional RSA; four overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections.
Heartscale *Atriplex cordulata* var. *cordulata*	–/–/1B.2	Saline or alkaline areas in chenopod scrub, meadows and seeps, sandy soils in valley and foothill grassland; below 560 meters	14 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Hispid salty bird's-beak *Chloropyron molle* ssp. *hispidum*	–/–/1B.1	Meadow and seeps, valley and foothill grassland, playa, on alkaline soils; 1-155 meters	28 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for all subsections.
Hoover's cryptantha *Cryptantha hooveri*	–/–/1A	Coarse, sandy soil in valley and foothill grassland; 9-150 meters	One CNDDB specific extant occurrence polygon in regional RSA does not overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass and San Joaquin Valley Subsections.
Hoover's spurge *Euphorbia hooveri*	FT/–/1B.2	Below the high-water mark of large northern hardpan and volcanic vernal pools; 25-250 meters	One occurrence polygon in regional RSA does not overlap with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Hoover's button-celery *Eryngium aristulatum* var. *hooveri*	–/–/1B.1	Vernal pools; 3-45 meters	Three CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy Subsection.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Hospital Canyon larkspur *Delphinium californicum* ssp. *interius*	–/–/1B.2	Openings in chaparral, mesic cismontane woodland, on moist slopes and ravines; 195-1,095 meters	10 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Indian Valley bush-mallow *Malacothamnus aboriginum*	–/–/1B.2	Granitic rocky areas in chaparral and oak woodland, often in burned areas; 150-1,700 meters	Two CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy Subsection.
Legenere *Legenere limosa*	–/–/1B.1	Deep, seasonally wet habitats such as vernal pools, ditches, marsh edges, and river banks; below 880 meters	One CNDDB specific extant occurrence polygons in regional RSA does not overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Lemmon's jewelflower *Caulanthus lemmonii*	–/–/1B.2	Dry, exposed slopes in grasslands and pinyon-juniper woodland; 80-1,220 meters	Four CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass Subsection.
Lesser saltscale *Atriplex minuscula*	–/–/1B.1	Sandy alkaline soils in chenopod scrub, playas, valley and foothill grassland; 15-200 meters	Five CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Lime Ridge navarretia *Navarretia gowenii*	–/–/1B.1	Chaparral; 180-305 meters	One CNDDB specific extant occurrence polygons in regional RSA does not overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass Subsection.
Little mousetail *Myosurus minimus* ssp. *apus*	–/–/3.1	Valley and foothill grassland, alkaline vernal pools; 20-640 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Loma Prieta hoita *Hoita strobilina*	–/–/1B.1	On mesic usually serpentinite substrates in chaparral, cismontane woodland, and riparian woodland; 30-860 meters	25 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy Subsection.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Lost Hills crownscale *Atriplex coronata* var. *vallicola*	–/–/1B.2	Alkaline soils in chenopod scrub, valley and foothill grassland, vernal pools; 50-635 meters	Two CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass and San Joaquin Valley Subsections.
Metcalf Canyon jewelflower *Streptanthus albidus ssp. albidus*	FE/–/1B.1	Valley and foothill grassland, on serpentinite; 45-800 meters	33 CNDDB specific extant occurrence polygons in the regional RSA; one overlaps with special-status plant study area at Communication Hill in the Monterey Corridor Subsection. Modeled habitat present in the special-status plant study area for Monterey Corridor and Morgan Hill and Gilroy Subsections.
Most beautiful jewelflower *Streptanthus albidus* ssp. *peramoenus*	–/–/1B.2	On serpentinite outcrops in chaparral, cismontane woodland, valley and foothill grassland, on ridges and slopes; 95-1,000 meters	49 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Monterey Corridor and Morgan Hill and Gilroy Subsections.
Mount Diablo cottonweed *Micropus amphibolus*	–/–/3.2	Rocky sites in broadleafed upland forest, mixed evergreen forest, oak woodland, chaparral, valley and foothill grasslands; 45-825 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for Pacheco Pass Subsection.
Mount Hamilton fountain thistle *Cirsium fontinale* var. *campylon*	–/–/1B.2	Freshwater seeps and streams on serpentinite outcrops, chaparral, cismontane woodland, valley and foothill grassland; 100-890 meters	38 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Palmate-bracted bird's-beak *Chloropyron palmatum*	FE/SE/1B.1	Alkaline sites (wetlands) in grassland and chenopod scrub; 5-155 meters	No known occurrences in regional RSA. Modeled habitat present in San Joaquin Valley Subsection.
Pink creamsacs *Castilleja rubicundula* var. *rubicundula*	–/–/1B.2	Serpentine soils in chaparral openings, cismontane woodland, meadows and seeps, and valley and foothill grassland; 20-910 meters	No known occurrences in regional RSA. Modeled habitat present in the Morgan Hill and Gilroy Subsection.
Prostrate vernal pool navarretia *Navarretia prostrata*	–/–/1B.1	Vernal pools and mesic areas in coastal scrub and alkali grasslands; 15-1,210 meters	Nine CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Recurved larkspur *Delphinium recurvatum*	–/–/1B.2	Alkaline soils in valley and foothill grassland, saltbush scrub, cismontane woodland; 3-790 meters	Seven CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass and San Joaquin Valley Subsections.
Round-leaved filaree *California macrophylla*	–/–/1B.1	Cismontane woodland, valley and foothill grassland on clay soils; 15-1,200 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.
Saline clover *Trifolium hydrophilum*	–/–/1B.2	Salt marsh, mesic alkaline areas in valley and foothill grasslands, vernal pools, marshes and swamps; below 300 meters	Six CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Jose Diridon Station Approach, Monterey Corridor, and Morgan Hill and Gilroy Subsections.
San Antonio Hills monardella *Monardella antonina* ssp. *antonina*	–/–/3	Chaparral, oak woodland, open rocky slopes; 320-1,000 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
San Francisco collinsia *Collinsia multicolor*	–/–/1B.2	Closed-cone coniferous forest, coastal scrub; 30-250 meters	Four CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Jose Diridon Station Approach, Monterey Corridor, and Morgan Hill and Gilroy Subsections.
San Joaquin Orcutt grass *Orcuttia inaequalis*	FT/SE/1B.1	Vernal pools; 10-755 meters	20 CNDDB specific extant occurrence polygons in the regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
San Joaquin spearscale *Extriplex joaquinana*	–/–/1B.2	Alkaline soils in chenopod scrub, meadows and seeps, playas, valley and foothill grassland; 1-835 meters	Six CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Jose Diridon Station Approach, Monterey Corridor, Morgan Hill and Gilroy, and San Joaquin Valley Subsections.
Sanford's arrowhead *Sagittaria sanfordii*	–/–/1B.2	Freshwater marshes, sloughs, canals, and other slow-moving water habitats; below 650 meters	Eight CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass and San Joaquin Valley Subsections.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Santa Clara Valley dudleya *Dudleya abramsii ssp. setchellii*	FE/–/1B.1	On rocky serpentinite sites in cismontane woodland, valley and foothill grassland; 60-455 meters	55 CNDDB specific extant occurrence polygons in the regional RSA; one overlaps with special-status plant study area north of Dana Rock Park (CNDDB occurrence 12) in Monterey Corridor Subsection. Modeled habitat present in the special-status plant study area for Monterey Corridor and Morgan Hill and Gilroy Subsections.
Shining navarretia *Navarretia nigelliformis* ssp. *radians*	–/–/1B.2	Mesic areas with heavy clay soils, in swales and clay flats, in oak woodland, grassland; 76-1,000 meters	34 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Pacheco Pass Subsection.
Showy golden madia *Madia radiata*	–/–/1B.1	Oak woodland, valley and foothill grassland, slopes; 25-1,215 meters	One CNDDB specific extant occurrence polygons in regional RSA does not overlap with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Slender-leaved pondweed *Stuckenia filiformis* ssp. *alpina*	–/–/2B.2	Freshwater marsh, shallow emergent wetlands and freshwater lakes, drainage channels; 300-2,150 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Smooth lessingia *Lessingia micradenia* var. *glabrata*	–/–/1B.2	On serpentinite in chaparral, oak woodland, often on roadsides; 120-420 meters	41 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections.
Tiburon paintbrush *Castilleja affinis* var. *neglecta*	FE/ST/1B.2	Serpentine grasslands; 60-400 meters	Two specific extant occurrence polygons in the regional RSA; none overlaps with special-status plant study area. Habitat was not modeled due to uncertainty of habitat parameters.
Two-fork clover *Trifolium amoenum*	FE/–/1B.1	Coastal bluff scrub, valley and foothill grasslands (sometimes serpentine); 5-415 meters	No known occurrences in regional RSA. Modeled habitat present in the Morgan Hill and Gilroy Subsection.
Vernal barley *Hordeum intercedens*	–/–/3.2	Coastal dunes, coastal scrub, vernal pools, saline streambeds, alkali flats, saline flats and depressions in valley and foothill grassland; 5-1,000 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.

Common Name *Scientific Name*	Status[1] Federal/State/CRPR	General Habitat Description	Occurrence in Regional RSA
Vernal pool smallscale *Atriplex persistens*	–/–/1B.2	Dry beds of vernal pools on alkaline soils; 10-115 meters	16 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.
Woodland woollythreads *Monolopia gracilens*	–/–/1B.2	Serpentinite soils in openings in broadleafed upland forest, chaparral, cismontane woodland, North Coast coniferous forest, and valley and foothill grassland; 100-1,200 meters	25 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Woolly-headed lessingia *Lessingia hololeuca*	–/–/3	Clay or serpentinite soils of broadleafed upland forest, coastal scrub, lower montane coniferous forest, valley and foothill grassland; 15-305 meters	No known occurrences in regional RSA. Modeled habitat present in special-status plant study area for Morgan Hill and Gilroy Subsection.
Wright's trichocoronis *Trichocoronis wrightii* var. *wrightii*	–/–/2B.1	On alkaline soils in floodplains, meadows and seeps, marshes and swamps, riparian forest, vernal pools; 5-435 meters	Two CNDDB specific extant occurrence polygons in regional RSA; one overlaps with special-status plant study area. Modeled habitat present in special-status plant study area for San Joaquin Valley Subsection.

[1] Species Status:
– = No status designation
Federal
FD = Delisted. Status to be monitored for 5 years.
FE = Listed as endangered under the federal Endangered Species Act.
FT = Listed as threatened under the federal Endangered Species Act.
State
SE = Listed as endangered under the California Endangered Species Act.
ST = Listed as threatened under the California Endangered Species Act.
SR = Listed as rare under the California Endangered Species Act.
SSC = California Species of Special Concern

CRPR (California Rare Plant Rank)
1A = Presumed extinct in California
1B = Rare, threatened, or endangered in California and elsewhere
2B = Rare, threatened, or endangered in California, but more common elsewhere
3 = More information needed about this plant (Review List).
.1: Seriously endangered in California
.2: Fairly endangered in California
.3: Not very endangered in California

Table 2 Special-Status Wildlife Species Potentially Subject to Project Impacts

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Invertebrates			
Monarch butterfly *Danaus plexippus*	C/–	Occurs throughout the United States and Canada where milkweed species (Asclepias spp.), their host plants, are present. Habitat includes breeding, migratory, and overwintering sites with both milkweed plants as well as other floral resources (nectar sources). Milkweed plants and other floral resources can be found in a variety of natural and manipulated landscapes. Overwintering sites occur in coastal California on groves of trees generally very close to the ocean or San Francisco Bay.	Only overwintering sites are currently tracked in CNDDB and none occur within the RSA. Numerous records from a variety of sources indicate that milkweed plants and monarch butterflies are present in the RSA.
Bay checkerspot butterfly *Euphydryas editha bayensis*	FT(CH)/–	Occurs in serpentine grassland vegetation in Santa Clara and San Mateo Counties. Primary host plant is dwarf plantain (*Plantago erecta*); secondary host plants are purple owl's-clover (*Castilleja densiflora*) and exserted paintbrush (*Castilleja exserta*) Physical or biological features of critical habitat include annual or perennial grassland with little or no overstory that provide north–south and east–west slopes with a tilt of no more than 7 degrees for larval host plant survival during atypical weather; the primary host plant and at least one secondary host plant; adult nectar sources for feeding; soils derived from serpentine rock; and stable holes and cracks in the soil, and rock outcrops that provide shelter for larvae during summer diapause.	11 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with HSA at Tulare Hill in the Santa Clara Valley (CDFW 2016a). Modeled habitat present in HSA for Monterey Corridor and Morgan Hill and Gilroy Subsections. Designated critical habitat present in Morgan Hill and Gilroy Subsection; Tulare Hill Unit (Unit 6) overlaps with HSA at Monterey Road and Metcalf Road; San Marin Unit (Unit 12) includes several network upgrade sites.
Crotch bumble bee *Bombus crotchii*	–/SCE	Open grassland and scrub in the Mediterranean region of California from along the Pacific Coast through the Inner Coast ranges and Great Central Valley into the Sierra foothills and the western portion of the Mohave Desert. Nests underground. Little known about overwintering sites but likely overwinters in soft, disturbed soils or under leaf litter or other ground debris like other bumble bees. Feeds on nectar and pollen from a variety of flowering plants, primarily those in the plant families Fabaceae, Apocynaceae, Asteraceae, Lamiaceae, and Boraginaceae.	One CNDDB specific occurrence polygon in regional RSA that does not overlap with HSA. One verified iNaturalist observation[2] in regional RSA west of Santa Teresa County Park in south San Jose that also does not overlap with HSA (2.5 miles outside project footprint). Modeled habitat present in HSA for all subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Conservancy fairy shrimp *Branchinecta conservatio*	FE(CH)/–	Found in large, deep, and turbid pools in the northern 2/3 of the Central Valley; inhabit pools located in swales formed by old, braided alluvium, filled by winter/spring rains, which last until June. Physical or biological features of critical habitat include topographic features characterized by mounds and swales and depressions within a matrix of surrounding uplands that result in continuous, or intermittently, flowing surface water connecting depressional features with underlying restrictive soil layers that become inundated by winter rains and continuously hold water for a minimum of 19 days; sources of food (e.g., single-celled bacteria and algae) in the pools; and structure in the pools consisting of organic and inorganic materials (e.g., living and dead plants, rocks) that provide shelter.	13 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for San Joaquin Valley Subsection.
Longhorn fairy shrimp *Branchinecta longiantenna*	FE(CH)/–	Endemic to the eastern margin of the central Coast Range in vernal pool grassland. Inhabit small, clear-water depressions in sandstone and clear-to-turbid clay/grass-bottomed pools in shallow swales. Physical or biological features of critical habitat include topographic features characterized by mounds and swales and depressions within a matrix of surrounding uplands that result in continuous, or intermittently, flowing surface water connecting depressional features with underlying restrictive soil layers that become inundated by winter rains and continuously hold water for a minimum of 23 days; sources of food (e.g., single-celled bacteria and algae) in the pools; and structure in the pools consisting of organic and inorganic materials (e.g., living and dead plants, rocks) that provide shelter.	Two specific extant occurrence polygons in regional RSA, associated with entire GEA; one overlaps with HSA. Modeled habitat present in HSA for San Joaquin Valley Subsection.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Vernal pool fairy shrimp *Branchinecta lynchi*	FT(CH)/–	Found in vernal pools, small clear-water sandstone depression pools, and grassy swales within annual grasslands throughout the central valley and central and south coast ranges. Physical or biological features of critical habitat include topographic features characterized by mounds and swales and depressions within a matrix of surrounding uplands that result in continuous, or intermittently, flowing surface water connecting depressional features with underlying restrictive soil layers that become inundated by winter rains and continuously hold water for a minimum of 18 days; sources of food (e.g., single-celled bacteria and algae) in the pools; and structure in the pools consisting of organic and inorganic materials (e.g., living and dead plants, rocks) that provide shelter.	182 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for San Joaquin Valley Subsection.
Vernal pool tadpole shrimp *Lepidurus packardi*	FE(CH)/–	Found in large vernal pools underlain by hardpan or in sandstone depressions; water in the vernal pools tends has very low alkalinity and conductivity. Physical or biological features of critical habitat include topographic features characterized by mounds and swales and depressions within a matrix of surrounding uplands that result in continuous, or intermittently, flowing surface water connecting depressional features with underlying restrictive soil layers that become inundated by winter rains and continuously hold water for a minimum of 18 days; sources of food (e.g., single-celled bacteria and algae) in the pools; and structure in the pools consisting of organic and inorganic materials (e.g., living and dead plants, rocks) that provide shelter.	47 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.
Valley elderberry longhorn beetle *Desmocerus californicus dimorphus*	FT/–	Streamside and oak savannah habitats throughout the Central Valley. Host plant is the elderberry shrub for larval development and adult forage. Stems measuring greater than 1 inch diameter are considered suitable habitat. Species always found close to host plant. Larvae may remain in stems for as long as 2 years.	Five CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Pacheco Pass and San Joaquin Valley Subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Fish			
Pacific lamprey *Entosphenus tridentatus*	–/SSC	In California, occurs along the coast and in coastal and estuarine streams from Los Angeles and Del Norte Counties and the rivers in the Central Valley. Upstream range limited by impassable barriers such as dams on major Central Valley rivers. Requires cold, clear water for spawning and incubation.	No CNDDB occurrences in regional RSA but known to occur in accessible reaches below dams in the Coyote Creek, Guadalupe River, Pajaro River, and San Joaquin River watersheds in the San Jose Diridon Station Approach, Monterey Corridor, and Morgan Hill and Gilroy Subsections.[3] Modeled habitat present in HSA for all subsections.
Steelhead – Central California Coast and South-Central California Coast DPSs *Oncorhynchus mykiss*	FT(CH)/–	Cold, clear water with clean gravel of appropriate size for spawning. Most spawning occurs in headwater streams. Steelhead migrate to the ocean to feed and grow until sexually mature. Physical or biological features of critical habitat include migration corridors to and from spawning areas that are free of barriers and maintain proper flow and water quality; freshwater spawning and rearing areas of high water quality and suitable substrate and forage; and estuarine and near-shore rearing areas of suitable water quality and forage.	Modeled habitat present in HSA for Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections. Designated critical habitat present in Morgan Hill and Gilroy and Pacheco Pass Subsections.
Chinook salmon – Central Valley Fall-/Late Fall-Run ESU[4] *Oncorhynchus tshawytscha*	EFH/SSC	Central Valley rivers and tributaries below impassable barriers. Adults enter rivers from San Francisco Estuary and move quickly to spawning grounds of cold, clear water with large gravel or cobble substrate. Peak spawning typically occurs October to November, but can continue through December and into January. Freshwater EFH for the Pacific salmon fishery (including chinook salmon) consists of four major components, 1) spawning and incubation; 2) juvenile rearing; 3) juvenile migration corridors; and 4) adult migration corridors and holding habitat.	San Joaquin River and its tributaries below impassable barriers. Designated freshwater EFH and modeled habitat present in Coyote Creek, Los Gatos Creek, and the Guadalupe River in the San Jose Diridon Station Approach, Monterey Corridor, and Morgan Hill and Gilroy Subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Amphibians			
California tiger salamander *Ambystoma californiense*	FT(CH)/ST	Annual grasslands and grassy understory of valley-foothill hardwood habitats (i.e., oak-savannah) with mammal burrows or other underground refugia. Requires vernal pools, small ponds, or lakes for breeding and mammal burrows or other underground refuges for cover during the dry season. Physical or biological features of critical habitat include: standing bodies of fresh water that become inundated during winter rains and typically hold water for a minimum of 12 weeks; upland habitat that contains small mammal burrows or other underground refugia; and upland dispersal habitat that allows for movement between occupied breeding sites.	261 CNDDB specific extant occurrence polygons in regional RSA; six overlap with HSA in Santa Clara Valley. Modeled habitat present in HSA for all subsections. Designated critical habitat present in Morgan Hill and Gilroy Subsection. Lions Peak Unit (Bay Area Geographic Region Units 10a and 10b) overlaps portion of PG&E Spring to Llagas and Green Valley to Llagas 115-kV power lines; San Felipe Unit (Bay Area Geographic Region Unit 12) overlaps with Tunnel 1.
California red-legged frog *Rana draytonii*	FT(CH)/SSC	Pools in marshes, streams, ponds, with emergent vegetation, and typically without predatory fish. In areas without year-round water or in colder temperatures, frogs require adequate hibernacula, such as small mammal burrows or moist leaf litter. Physical or biological features of critical habitat include standing bodies of fresh water that typically become inundated during winter rains and hold water for a minimum of 20 weeks; freshwater ponds and streams that may not hold water long enough to support the species' aquatic life cycle but that provide for shelter, foraging, predator avoidance, and aquatic dispersal of juveniles and adults; and upland areas adjacent to or surrounding breeding and non-breeding aquatic and riparian habitat up to a distance of 1 mile.	229 CNDDB specific extant occurrence polygons in regional RSA; five overlap with HSA: one at Ogier Ponds near Coyote Creek, one in Pacheco Creek near Casa de Fruta, two intermittent streams near Pacheco Pass, one at large pond northwest of San Luis Reservoir. Modeled habitat present in HSA for Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections. Designated critical habitat present in Morgan Hill and Gilroy and Pacheco Pass Subsections. Wilson Peak unit (Unit STC-2) overlaps with HSA at Tunnel 1 in Morgan Hill and Gilroy Subsection and between Casa de Fruta and San Luis Reservoir in Pacheco Pass Subsection.
Foothill yellow-legged frog *Rana boylii*	–/SCT;SSC	Foothills of the Sierra Nevada and Coast Range. Occurs in rocky streams and rivers with rocky substrate and open, sunny banks, in forests, chaparral, and woodlands. Cobble-sized substrate required for egg laying.	33 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Western spadefoot *Spea* (=*Scaphiopus*) *hammondii*	–/SSC	Open areas with sandy or gravelly soils in a variety of habitats within central valley, foothills, and south coast ranges. Breeds in vernal pools and other seasonal pools or swales.	48 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Reptiles			
Western pond turtle *Emys* (= *Clemmys* /*Actinemys*) marmorata	–/SSC	Inhabits ponds, marshes, rivers, streams, and irrigation ditches throughout the valley, foothills, and coast ranges of California. Needs basking sites such as partially submerged logs or rocks, and suitable upland habit (sandy banks or grassy open fields) for egg laying. Primarily in fresh water, may also enter brackish, or rarely saltwater.	134 CNDDB specific extant occurrence polygons in regional RSA; four overlap with HSA. Modeled habitat present in HSA for all subsections.
Blunt-nosed leopard lizard *Gambelia sila*	FE/SE;FP	Resident of sparsely vegetated grasslands, alkali flats, and washes within the San Joaquin valley. Prefers flat areas with open space for running, avoiding densely vegetated areas. Seek cover in mammal burrows, under shrubs or structures such as fence posts; do not excavate their own burrows. Semiarid grasslands, alkali flats, and washes.	Six CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA at eastern end of Pacheco Pass Subsection.
San Joaquin coachwhip *Masticophis flagellum ruddocki*	–/SSC	Open, dry, treeless areas, including grassland and saltbush scrub in western San Joaquin Valley. Takes refuge in rodent burrows, under shaded vegetation, and under surface objects.	19 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Northern California legless lizard *Anniella pulchra*	–/SSC	Semi-stabilized sand dunes, areas with sandy soil, and high moisture content, vegetated with oak or pine-oak woodland, chaparral; also wooded stream edges, and occasionally desert-scrub. Dunes with bush lupine and mock heather often indicate suitable conditions. Often found in leaf litter, under rocks, logs, and driftwood.	No known occurrences in regional RSA. Modeled habitat present in HSA for Morgan Hill and Gilroy and Pacheco Pass Subsections.
Coast (= Blainville's) horned lizard *Phrynosoma blainvillii*	–/SSC	Sandy or loose soils within grasslands, brushlands, woodlands, and open coniferous forest. Dietary specialists dependent on ants, as well as beetles and other seasonally abundant insects. Forage on the ground in open areas, usually between shrubs and often near an ant nest. Utilize small mammal burrows or burrow under surface objects during periods of extended inactivity or hibernation.	15 CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Morgan Hill and Gilroy and Pacheco Pass Subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Giant garter snake *Thamnophis gigas*	FT/ST	Found in freshwater marshes and low-gradient streams. Prefers habitat with dense emergent vegetation, deep and shallow pools of water (which persist throughout the seasonal cycle of activity), open areas along water margins, and upland habitat with access to structures suitable for hibernation and escape from flooding. Has adapted to drainage canals and irrigation ditches within agricultural areas.	28 CNDDB specific extant occurrence polygons in regional RSA; two overlap with HSA at GEA (CNDDB occurrences 23 and 161). Modeled habitat present in HSA for Pacheco Pass and San Joaquin Valley Subsections.
Birds			
Short-eared owl *Asio flammeus*	–/SSC	Year-round resident in California. Nests on ground within coastal and inland prairies, grasslands, meadows, marshes, and farmlands with abundant rodent populations.	No known occurrences in regional RSA. Modeled habitat present in HSA for Pacheco Pass and San Joaquin Valley Subsections.
Grasshopper sparrow *Ammodramus savannarum*	–/SSC	Summer resident in California from March to September. Occurs in short- to middle-height, moderately open grasslands with scattered shrubs.	No known CNDDB occurrences in regional RSA, but multiple reports in eBird.[4] Modeled habitat present in HSA for Pacheco Pass and San Joaquin Valley Subsections.
Mountain plover *Charadrius montanus*	–/SSC	Winter visitor to California range. Roost and forage in short grasslands, freshly plowed fields, and bare ground with flat topography. Prefers fallow, grazed, or burned areas and alkali flats with burrowing rodents.	Five CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for Pacheco Pass and San Joaquin Valley Subsections.
Western snowy plover (interior population) *Charadrius alexandrinus nivosus*	– (interior population)/SSC	Year-round resident in California. Nests at inland lakes throughout northeastern, central, and southern California, including Mono Lake and Salton Sea. Feeds primarily on terrestrial and aquatic invertebrates.	Two CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA.
Western burrowing owl *Athene cunicularia*	–/SSC	Year-round resident in lowlands throughout much of California. Migrants from other parts of western North America may augment resident populations in winter. Found in open, dry, annual or perennial grasslands, deserts, and scrublands characterized by low-growing vegetation. Uses small mammal burrows for nesting and winter refuge. May also use rock piles and culverts as roost sites	94 CNDDB specific extant occurrence polygons in regional RSA; four overlap with HSA. Modeled habitat present in HSA for all subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Golden eagle *Aquila chrysaetos*	–/FP	Permanent resident and migrant throughout California range. Found in mountains and foothills. Nests on cliff edges or large trees in open areas. Needs open terrain for hunting: grasslands, deserts, savannahs, and early successional stages of forest and shrub habitats.	Five CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for all subsections.
Bald eagle *Haliaeetus leucocephalus*	–/SE;FP	Mainly found in mountainous habitats near reservoirs, lakes, and rivers and builds nests in the upper canopy of large coniferous trees. Most nest within 1 mile of water.	Five CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA; San Luis Reservoir nest (CNDDB occurrence 365) 2.9 miles west of project footprint at Tunnel 2 east portal. Modeled habitat present in HSA for Morgan Hill and Gilroy and Pacheco Pass Subsections.
American peregrine falcon *Falco peregrinus anatum*	–/FP	Found year-round within California range in a variety of habitats, most with cliffs for nesting and open areas for foraging. Also uses large cities and nests on buildings.	Four CNDDB specific extant occurrence polygons in regional RSA; one overlaps with HSA. Modeled habitat present in HSA for all subsections.
Northern harrier *Circus cyaneus*	–/SSC	Occurs year-round within breeding range in California and may potentially winter in areas statewide. Breeds and forages in variety of open (treeless) habitats such as marshes, meadows, pastures, prairies, weedy borders of lakes, rivers, and streams, grasslands, some croplands, sagebrush flats, and desert sinks. Constructs nests on ground in open field or meadow in shrubby vegetation, usually near wet areas.	10 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with HSA. Modeled habitat present in HSA for all subsections.
White-tailed kite *Elanus leucurus*	–/FP	Found year-round within California range in grasslands, agricultural fields, oak woodlands, savannah, and riparian habitats in rural and urban areas. They are often found along tree-lined river valleys with adjacent open areas. Nest in trees.	Five CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for all subsections.
Swainson's hawk *Buteo swainsoni*	–/ST	South American migrant that breeds in Central Valley of California. Found in open country such as grassland, shrubland, and agricultural areas. Nests in riparian areas and oak woodlands as well as isolated and roadside trees close to grassland or agricultural foraging habitat.	193 CNDDB specific extant occurrence polygons in regional RSA; 8 overlap with HSA. Modeled habitat present in HSA for Monterey Corridor, Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
California condor *Gymnogyps californianus*	FE/SE;FP	Permanent resident of the semi-arid, rugged mountain ranges surrounding southern San Joaquin Valley. Nests in caves, crevices, behind rock slabs, or on large ledges on high sandstone cliffs.	No known occurrences in regional RSA; HSA study area within flying distance of Pinnacles Nat'l Park. Habitat not modeled for this species but Diablo Range could be used for foraging if the species' range expands.
Loggerhead shrike *Lanius ludovicianus*	–/SSC	Year-round throughout most of California range; some breeding populations may be migratory. Wintering individuals augment resident populations and occupy areas where none breed. Breeds and forages in open habitats interspersed with shrubs and small trees, including disturbed habitats. Nests placed in trees.	Three CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for all subsections.
Purple martin *Progne subis*	–/SSC	Summer resident and migrant in California. Uses wide variety of nesting substrates (e.g., tree cavities, bridges, utility poles, lava tubes, buildings); however, sites must have low canopy cover at nest height. Most tree nest sites located in upper slopes of hilly and mountainous terrain. Often found near large wetlands and other water bodies. Starlings are competitors and must be present in low densities or absent.	One CNDDB specific extant occurrence polygons in regional RSA does not overlap with HSA. Modeled habitat present in HSA for Pacheco Pass Subsection.
Olive-sided flycatcher *Contopus cooperi*	–/SSC	Summer resident and migrant in California primarily from mid-April through early October. Breeds in montane and northern coniferous forest, at edges and openings. Winters at forest edges and clearings with tall trees or snags.	No known occurrences in regional RSA. Modeled habitat present in HSA for Pacheco Pass Subsection.
Least Bell's vireo *Vireo bellii pusillus*	FE/SE	Summers within California range. Typically inhabits structurally diverse dense riparian woodlands/shrubs along water courses or near open water. Nests in shrub or low tree, usually about 3 feet above ground, in horizontal or down-sloping twig fork, typically near edge of thicket. Obligate riparian species during breeding season. Brown-headed cowbird severe threat.	Four CNDDB specific extant occurrence polygons in regional RSA; one overlaps with HSA near Gilroy (CNDDB occurrence 198). Modeled habitat present in HSA for all subsections. Modeled habitat present in HSA for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.
Yellow warbler *Setophaga petechia*	–/SSC	Riparian vegetation in close proximity to water along streams and in wet meadows.	No known CNDDB occurrences in regional RSA, but multiple reports in eBird,[4] several of which are in the HSA for the San Jose Diridon Station approach, Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections. Modeled habitat is present in these subsections, as well.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Yellow-breasted chat *Icteria virens*	–/SSC	Summer resident and migrant in California, primarily from late March to late September. Nests locally in coastal mountains and Sierra Nevada foothills, east of the Cascades in northern California, along the Colorado river, and very locally inland in southern California. Occurs in early successional riparian habitat with a well-developed shrub layer and open canopy.	No known CNDDB occurrences in regional RSA, but multiple reports in eBird,[4] several of which are in the HSA for the Morgan Hill and Gilroy Subsection. Modeled habitat present in HSA for the San Jose Diridon Station approach, Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections.
Tricolored blackbird *Agelaius tricolor*	—/SCE;SSC	Almost endemic to California; permanent resident and migrant. Highly colonial species, most numerous in Central Valley and vicinity. Nests next to open water typically in freshwater marsh habitat where there is extensive emergent or riparian vegetation. Increasing percentage of breeding colonies has been reported in grain fields. Forages in grasslands, wetland habitats, and some agricultural areas.	129 CNDDB specific extant occurrence polygons in regional RSA; six overlap with HSA. Modeled habitat present in HSA for all subsections.
Yellow-headed blackbird *Xanthocephalus xanthocephalus*	–/SSC	Mainly summer resident and migrant in California range; small numbers winter. Breeds in loose colonies in freshwater wetlands (e.g., marshes) with tall dense emergent vegetation adjacent to deep water, and along borders of lakes or ponds. Places its nest over water, attached to cattails and reeds. Forages in the wetlands and in surrounding grasslands and croplands. In winter large flocks forage in agricultural areas.	One CNDDB specific extant occurrence polygons in regional RSA does not overlap with HSA. Modeled habitat present in HSA for San Joaquin Valley Subsection.
Greater sandhill crane *Antigone canadensis tabida*	–/ST;FP	Migratory resident found in grassland, moist croplands, shallow lacustrine, and fresh emergent wetland habitats in the Sacramento and San Joaquin Valley. Breeding occurs in wetland and meadow habitat in Lassen, Modoc, Plumas, Shasta, Sierra, and Siskiyou counties.	No CNDDB occurrences in regional RSA, but multiple species-level reports in eBird,[4] including several locations in the HSA for the San Joaquin Valley Subsection. It is likely that at least some of the observed individuals belonged to the “greater” subspecies. Modeled habitat present in San Joaquin Valley Subsection.
Lesser sandhill crane *Antigone canadensis canadensis*	–/SSC	Winters and migrates through Central Valley and Imperial Valley, with main wintering concentrations in Merced County and Sacramento-San Joaquin River Delta. Forages on waste grains and other seeds in agricultural fields, pastures, and grassland. Does not breed in California.	No CNDDB occurrences in regional RSA, but multiple species-level reports in eBird,[4] including several locations in the HSA for the San Joaquin Valley Subsection. It is likely that most of the observed individuals belonged to the “lesser” subspecies. Modeled habitat present in San Joaquin Valley Subsection.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Mammals			
San Joaquin kit fox *Vulpes macrotis mutica*	FE/ST	Occurs in the San Joaquin Valley in annual grassland or grassy open stages with scattered shrubby vegetation; requires loose-textured sandy soils for burrowing; requires suitable prey base of small rodents, including kangaroo rats or California ground squirrels.	72 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with HSA. Modeled habitat present in HSA for Morgan Hill and Gilroy, Pacheco Pass, and San Joaquin Valley Subsections.
Fresno kangaroo rat *Dipodomys nitratoides exilis*	FE/SE	Restricted to native grasslands in Fresno County within the San Joaquin Valley; nearly level, light, friable soils in chenopod scrub and grassland communities.	No known occurrences in regional RSA. Modeled habitat present in HSA for San Joaquin Valley Subsection.
Mountain lion *Puma concolor*	–/SCT[5]	Occurs throughout most of California in grasslands, woodlands, and a variety of other habitats. Large ungulates, especially deer, are the primary prey; however, they are opportunistic predators feeding on a wide variety of other large and smaller prey.	The species is known to occur in the HSA. The Southern California/Central Coast ESU includes all areas in the HSA to the west of the Central Valley (generally those areas west of I-5).
American badger *Taxidea taxus*	–/SSC	Occurs throughout California in grasslands, savannas, and mountain meadows near timberline; requires friable soils and relatively open, uncultivated ground; requires suitable prey base of burrowing rodents such as gophers, ground squirrels, marmots, and kangaroo rats.	No known occurrences in regional RSA. Modeled habitat present in HSA for Pacheco Pass and San Joaquin Valley Subsections.
San Francisco dusky-footed woodrat *Neotoma fuscipes annectens*	–/SSC	Occurs in wooded habitats in San Francisco south through Santa Clara County.	Six CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for San Jose Diridon Station Approach, Monterey Corridor, Morgan Hill and Gilroy, and Pacheco Pass Subsections.
Ringtail *Bassariscus astutus*	–/FP	Occurs throughout California in dry, rocky, or mountainous areas with scattered oaks and conifers as well as riparian communities; requires hollow trees, logs, cavities in rocky areas, or other recesses for cover and breeding.	No known occurrences in regional RSA but species difficult to detect and therefore poorly represented in CNDDB.
Townsend's big-eared bat *Corynorhinus townsendii*	–/SSC	Found in a variety of habitats throughout California, most commonly in mesic sites, including coniferous forests, mixed mesophytic forests, deserts, native prairies, riparian communities, active agricultural areas, and coastal habitat types. Typically found in areas within caves and cave-like roosting habitat, such as mines, buildings, bridges and basal hollows in big old-growth trees.	15 CNDDB specific extant occurrence polygons in regional RSA; one overlaps with HSA. Modeled habitat present in HSA for all subsections.

Common Name *Scientific Name*	Status[1] Federal/State	Habitat	Occurrence in Regional RSA
Western mastiff bat *Eumops perotis californicus*	–/SSC	Roosts in crevices in cliff faces, high buildings, and tunnels; forages in arid, semi-arid habitat-coniferous and deciduous woodlands, coastal scrub, grasslands, and chaparral.	Six CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for all subsections.
Western red bat *Lasiurus blossevillii*	–/SSC	Occurs throughout California; roosts primarily in trees, typically adjacent to open fields or streams, which are protected above and open below for foraging; prefers habitat edges and mosaics with trees.	Six CNDDB specific extant occurrence polygons in regional RSA; none overlaps with HSA. Modeled habitat present in HSA for all subsections.

CNDDB = California Natural Diversity Database
DPS = distinct population segment
ESU = evolutionarily significant unit

APPENDIX 3.7-B: SCIENTIFIC NOMENCLATURE

Table 1 Scientific Nomenclature of All Species Mentioned in Text

Common Name	*Scientific Name*
Plants	
Alkali milkvetch	*Astragalus tener* var. *tener*
Anderson's manzanita	*Arctostaphylos andersonii*
Arburua Ranch jewelflower	*Streptanthus insignis* ssp. *lyonii*
Arcuate bush-mallow	*Malacothamnus arcuatus*
Bent-flowered fiddleneck	*Amsinckia lunaris*
Big-scale balsamroot	*Balsamorhiza macrolepis*
Bristly sedge	*Carex comosa*
Brittlescale	*Atriplex depressa*
California alkali grass	*Puccinellia simplex*
Caper-fruited tropidocarpum	*Tropidocarpum capparideum*
Chaparral harebell	*Campanula exigua*
Chaparral ragwort	*Senecio aphanactis*
Colusa grass	*Neostapfia colusana*
Congdon's tarplant	*Centromadia parryi* ssp. *congdonii*
Coulter's goldfields	*Lasthenia glabrata* ssp. *coulteri*
Coyote ceanothus	*Ceanothus ferrisiae*
Delta button-celery	*Eryngium racemosum*
Eucalyptus	*Eucalyptus* spp.
Fragrant fritillary	*Fritillaria liliacea*
Giant reed	*Arundo donax*
Greene's tuctoria	*Tuctoria greenei*
Hairless popcornflower	*Plagiobothrys glaber*
Hairy Orcutt grass	*Orcuttia pilosa*
Hall's bush-mallow	*Malacothamnus hallii*
Heartscale	*Atriplex cordulata* var. *cordulata*
Hispid salty bird's-beak	*Chloropyron molle* ssp. *hispidum*
Hooker's manzanita	*Arctostaphylos hookeri* ssp. *hookeri*
Hoover's cryptantha	*Cryptantha hooveri*
Hoover's spurge	*Euphorbia hooveri*
Hoover's button-celery	*Eryngium aristulatum* var. *hooveri*
Hospital Canyon larkspur	*Delphinium californicum* ssp. *interius*
Indian Valley bush-mallow	*Malacothamnus aboriginum*

Common Name	*Scientific Name*
Kings Mountain manzanita	*Arctostaphylos regismontana*
Legenere	*Legenere limosa*
Lemmon's jewelflower	*Caulanthus lemmonii*
Lesser saltscale	*Atriplex minuscula*
Lime Ridge navarretia	*Navarretia gowenii*
Little mousetail	*Myosurus minimus* ssp. *apus*
Loma Prieta hoita	*Hoita strobilina*
Lost Hills crownscale	*Atriplex coronata* var. *vallicola*
Marsh microseris	*Microseris paludosa*
Merced phacelia	*Phacelia ciliata* var. *opaca*
Metcalf Canyon jewelflower	*Streptanthus albidus ssp. albidus*
Most beautiful jewelflower	*Streptanthus albidus* ssp. *peramoenus*
Mount Diablo cottonweed	*Micropus amphibolus*
Mount Hamilton fountain thistle	*Cirsium fontinale* var. *campylon*
Mount Hamilton jewelflower	*Streptanthus callistus*
Pajaro manzanita	*Arctostaphylos pajaroensis*
Palmate-bracted bird's-beak	*Chloropyron palmatum*
Pink creamsacs	*Castilleja rubicundula* var. *rubicundula*
Pinnacles buckwheat	*Eriogonum nortonii*
Prostrate vernal pool navarretia	*Navarretia prostrata*
Recurved larkspur	*Delphinium recurvatum*
Rock sanicle	*Sanicula saxatilis*
Round-leaved filaree	*California macrophylla*
Saline clover	*Trifolium hydrophilum*
San Antonio Hills monardella	*Monardella antonina* ssp. *antonina*
San Francisco collinsia	*Collinsia multicolor*
San Joaquin Orcutt grass	*Orcuttia inaequalis*
San Joaquin spearscale	*Extriplex joaquinana*
Sanford's arrowhead	*Sagittaria sanfordii*
Santa Clara Valley dudleya	*Dudleya abramsii ssp. setchellii*
Santa Cruz clover	*Trifolium buckwestiorum*
Santa Cruz Mountains beardtongue	*Penstemon rattanii* var. *kleei*
Shining navarretia	*Navarretia nigelliformis* ssp. *radians*
Showy golden madia	*Madia radiata*
Slender-leaved pondweed	*Stuckenia filiformis* ssp. *alpina*

Common Name	*Scientific Name*
Smooth lessingia	*Lessingia micradenia* var. *glabrata*
Spiny-sepaled button-celery	*Eryngium spinosepalum*
Subtle orache	*Atriplex subtilis*
Succulent owl's-clover	*Castilleja campestris* var. *succulenta*
Tamarisk	*Tamarisk* sp.
Tiburon paintbrush	*Castilleja affinis* var. *neglecta*
Vernal barley	*Hordeum intercedens*
Vernal pool smallscale	*Atriplex persistens*
Western Heermann's buckwheat	*Eriogonum heermannii* var. *occidentale*
Woodland woollythreads	*Monolopia gracilens*
Woolly-headed lessingia	*Lessingia hololeuca*
Wright's trichocoronis	*Trichocoronis wrightii* var. *wrightii*
Invertebrates	
Bay checkerspot butterfly	*Euphydryas editha bayensis*
Conservancy fairy shrimp	*Branchinecta conservatio*
Longhorn fairy shrimp	*Branchinecta longiantenna*
Monarch butterfly	*Danaus plexippus*
Vernal pool fairy shrimp	*Branchinecta lynchi*
Vernal pool tadpole shrimp	*Lepidurus packardi*
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*
Fish	
Pacific lamprey	*Entosphenus tridentatus*
Steelhead – Central California Coast and South-Central California Coast DPSs	*Oncorhynchus mykiss*
Chinook salmon – Central Valley Fall-Run ESU[4]	*Oncorhynchus tshawytscha*
Amphibians	
Arboreal salamander	*Aneides lugubris*
California newt	*Taricha torosa*
California slender salamander	*Batrachoseps attenuatus*
Ensatina	*Ensatina eschscholtzii*
California tiger salamander	*Ambystoma californiense*
Sierran treefrog	*Pseudacris sierra*
California red-legged frog	*Rana draytonii*
Foothill yellow-legged frog	*Rana boylii*
Western toad	*Bufo boreas*

Common Name	*Scientific Name*
Western spadefoot	*Spea* (=*Scaphiopus*) *hammondii*
Reptiles	
Western pond turtle	*Emys* (= *Clemmys* /*Actinemys*) marmorata
Western fence lizard	*Sceloporus occidentalis*
Blunt-nosed leopard lizard	*Gambelia sila*
Northern California legless lizard	*Anniella pulchra*
Coast (= Blainville's) horned lizard	*Phrynosoma blainvillii*
Southern alligator lizard	*Elgaria multicarinata*
Northern rubber boa	*Charina bottae*
Common sharp-tailed snake	*Contia tenuis*
Ring-necked snake	*Diadophis punctatus*
San Joaquin whipsnake	*Masticophis flagellum ruddocki*
Striped racer	*Coluber lateralis*
Common garter snake	*Thamnophis sirtalis*
Giant garter snake	*Thamnophis gigas*
California kingsnake	*Lampropeltis californiae*
Gopher snake	*Pituophis catenifer*
Western rattlesnake	*Crotalus oreganus*
Birds	
Greater white-fronted goose	*Anser albifrons*
Snow goose	*Anser caerulescens*
Ross's goose	*Anser rossii*
Cackling goose	*Branta hutchinsii*
Canada goose	*Branta canadensis*
Tundra swan	*Cygnus columbianus*
Gadwall	*Mareca strepera*
Cinnamon teal	*Spatula cyanoptera*
Northern shoveler	*Spatula clypeata*
Green-winged teal	*Anas crecca*
Mallard	*Anas platyrhynchos*
Northern pintail	*Anas acuta*
Redhead	*Aythya americana*
Canvasback	*Aythya valisineria*
Ring-necked duck	*Aythya collaris*
Greater scaup	*Aythya marila*

Common Name	*Scientific Name*
Bufflehead	*Bucephala albeola*
Ruddy duck	*Oxyura jamaicensis*
Western grebe	*Aechmophorus occidentalis*
Western yellow-billed cuckoo	*Coccyzus americanus*
White-throated swift	*Aeronautes saxatalis*
Anna's hummingbird	*Calypte anna*
Black rail	*Laterallus jamaicensis*
Virginia rail	*Rallus limicola*
Sora	*Porzana carolina*
Greater sandhill crane	*Antigone canadensis tabida*
Lesser sandhill crane	*Antigone canadensis canadensis*
American avocet	*Recurvirostra americana*
Western snowy plover (interior population)	*Charadrius alexandrinus nivosus*
Killdeer	*Charadrius vociferus*
Mountain plover	*Charadrius montanus*
Whimbrel	*Numenius phaeopus*
Dunlin	*Calidris alpina*
Least sandpiper	*Calidris minutilla*
Western sandpiper	*Calidris mauri*
Long-billed dowitcher	*Limnodromus scolopaceus*
Spotted sandpiper	*Actitis macularia*
Greater yellowlegs	*Tringa melanoleuca*
California gull	*Larus californicus*
Black tern	*Chlidonias niger*
Forster's tern	*Sterna forsteri*
Great blue heron	*Ardea herodis*
Great egret	*Ardea alba*
Snowy egret	*Egretta thula*
Little blue heron	*Egretta caerulea*
Cattle egret	*Bubulcus ibis*
Black-crowned night-heron	*Nycticorax nycticorax*
White-faced ibis	*Plegadis chihi*
California condor	*Gymnogyps californianus*
White-tailed kite	*Elanus leucurus*
Bald eagle	*Haliaeetus leucocephalus*

Common Name	*Scientific Name*
Northern harrier	*Circus cyaneus*
Cooper's hawk	*Accipiter cooperi*
Red-shouldered hawk	*Buteo lineatus*
Red-tailed hawk	*Buteo jamaicensis*
Swainson's hawk	*Buteo swainsoni*
Golden eagle	*Aquila chrysaetos*
Great horned owl	*Bubo virigianaus*
Western burrowing owl	*Athene cunicularia*
Short-eared owl	*Asio flammeus*
Nuttall's woodpecker	*Picoirdes nuttallii*
Downy woodpecker	*Picoides pubescens*
American peregrine falcon	*Falco peregrinus anatum*
Olive-sided flycatcher	*Contopus cooperi*
Pacific-slope flycatcher	*Empidonax difficilis*
Black phoebe	*Sayornis nigricans*
Loggerhead shrike	*Lanius ludovicianus*
Least Bell's vireo	*Vireo bellii pusillus*
Hutton's vireo	*Vireo huttoni*
Warbling vireo	*Vireo gilvus*
California scrub-jay	*Aphelocoma californica*
American crow	*Corvus brachyrhynchos*
Purple martin	*Progne subis*
Cliff swallow	*Petrochelidon pyrrhonota*
Barn swallow	*Hirundo rustica*
Oak titmouse	*Baeolophus inornatus*
Bushtit	*Psaltriparus minimus*
White-breasted nuthatch	*Sitta carolinensis*
Marsh wren	*Cistothorus palustris*
Northern mockingbird	*Mimus polyglottos*
House finch	*Haemorhous mexicanus*
Spotted towhee	*Pipilo maculatus*
California towhee	*Melozone crissalis*
Grasshopper sparrow	*Ammodramus savannarum*
Song sparrow	*Melospiza melodia*
Yellow-breasted chat	*Icteria virens*

Common Name	*Scientific Name*
Yellow-headed blackbird	*Xanthocephalus xanthocephalus*
Western meadowlark	*Sturnella neglecta*
Red-winged blackbird	*Agelaius phoeniceus*
Tricolored blackbird	*Agelaius tricolor*
Orange-crowned warbler	*Oreothlypis celata*
Common yellowthroat	*Geothlypis trichas*
Yellow warbler	*Setophaga petechia*
Black-headed grosbeak	*Pheucticus melanocephalus*
Mammals	
Virginia opossum	*Didelphis virginiana*
Big brown bat	*Eptesicus fuscus*
Townsend's big-eared bat	*Corynorhinus townsendii*
Hoary bat	*Lasiurus cinereus*
Western red bat	*Lasiurus blossevillii*
California myotis	*Myotis californicus*
Pallid bat	*Antrozous pallidus*
Western mastiff bat	*Eumops perotis californicus*
Mexican free-tailed bat	*Tadarida brasiliensis*
Western gray squirrel	*Sciurus griseus*
California ground squirrel	*Spermophilus beecheyi*
Merriam's chipmunk	*Tamias merriami*
Botta's pocket gopher	*Thomomys bottae*
Fresno kangaroo rat	*Dipodomys nitratoides exilis*
House mouse	*Mus musculus*
California vole	*Microtus californicus*
California deer mouse	*Peromyscus californicus*
Western harvest mouse	*Reithrodontomys megalotis*
San Francisco dusky-footed woodrat	*Neotoma fuscipes annectens*
Gray fox	*Urocyon cinereoargenteus*
San Joaquin kit fox	*Vulpes macrotis mutica*
Coyote	*Canis latrans*
Northern raccoon	*Procyon lotor*
Ringtail	*Bassariscus astutus*
American badger	*Taxidea taxus*
Striped skunk	*Mephitis mephitis*

Common Name	*Scientific Name*
Bobcat	*Lynx rufus*
Mountain lion	*Puma concolor*
Mule deer	*Odocoileus hemionus*

APPENDIX 3.7-C: HSR GUIDEWAY ENCLOSURE FOR THE GRASSLANDS ECOLOGICAL AREA

Confidential/Internal Use

MEMORANDUM

Date: November 5, 2019

To: Gary Kennerley

From: Julian Bratina

CC: Dave Shpak

Subject: HSR Guideway Enclosure for the Grasslands Ecological Area

---

Introduction

This memorandum summarizes the efforts by the Authority to develop, analyze and review conceptual design options for an acoustic guideway enclosure. An enclosure that surrounds the train operating envelope and OCS equipment would provide a greater reduction in noise, visual, and bird strike impacts than noise barriers and line markers where the alignment passes through an important complex of wetlands. The Authority Director of Environmental Services commissioned this analysis in response to a request from the Grassland Water District and other stakeholders in the Grasslands Ecological Area.

Background

During the program level route identification efforts, the Authority selected an alignment across the Grasslands Ecological Area (GEA), a complex of wetlands measuring approximately 95,000 hectares in the San Joaquin Valley, at the narrowest point to minimize the impact of high-speed rail (HSR) on the area. The results of these efforts were published in the Bay Area to Central Valley HST Final EIR/S 2008 environmental document. During this program environmental stage, CHSRA committed to place approximately 3.0 miles of guideway on an elevated structure centered on Mud Slough to minimize the impact on the GEA.

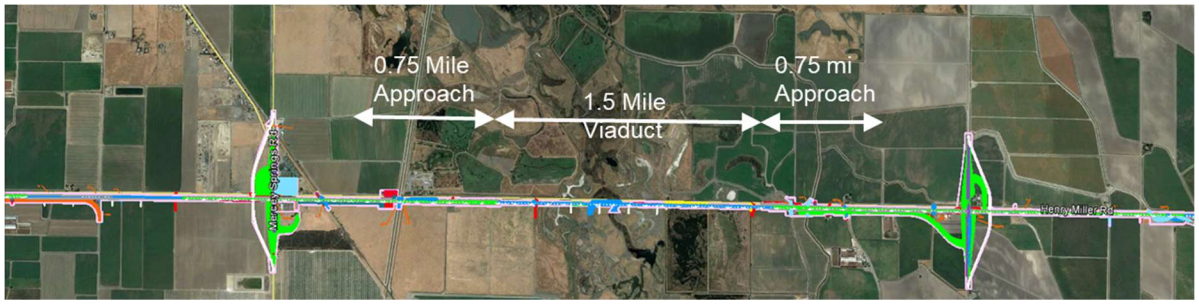

Figure 1: Extent of HSR guideway across Grasslands Ecological Area

The Authority has been working with stakeholders in the GEA to evaluate the environmental impact of this decision, and potential methods of mitigation. In December of 2018, the Authority received a letter from the GEA Working Group that requested consideration of an enclosure structure similar to that used in China's Shenzen-Maoming HSR program. This is a structure that would fully enclose the guideway and overhead contact system, to mitigate visual and acoustic impacts on waterfowl and shorebirds living in and moving across the adjacent habitat.

Figure 2: Chenzen-Maoming Guideway Enclosure

Coincidentally, preliminary results of the Authority's ongoing evaluation of impacts to waterfowl and shorebirds in the GEA Important Bird Area proximate to Mud Slough indicated potential for visual, noise, and bird-strike impacts. The Authority agreed to evaluate the enclosure concept, determine whether a similar structure would be suitable for the GEA crossing, and what the structure's potential impacts would be.

Analysis

1. Design Development

The Engineering team evaluated the tubular concept, and produced a similar design that would enclose the guideway and the full extents of the CHSRA operating envelope. The structure primarily consisted of steel w-flange beams rolled into a circular shape, bolted together with gusset plates, and supported on the concrete viaduct structure. A circular steel frame would support precast concrete panels mounted around the structure, with OCS brackets hung inside the structure, and longitudinally reinforced by steel struts. The design concepts were subjected to preliminary structural assessments, including wind loading, support of OCS equipment, the loading on the viaduct structure, and considered different material types for sound attenuation.

There were two primary objectives of the enclosure: (1) to avoid the visual and acoustic impacts on waterfowl and shorebirds, and (2) to prevent bird strikes. While a noise barrier would encourage birds to fly higher over the guideway, it would not prevent nesting, foraging, or roosting within the operating envelope of the train. Also, the OCS equipment would protrude above the noise barriers and attract perching, and create a deadly obstacle to avian flight paths. A permeable enclosure was explored to preclude avian access, but discarded due to its inability to reduce acoustic and visual impacts, and the unacceptable maintenance challenges.

After the design and performance analyses revealed considerable weight and cost, the engineering team designed an alternative concept with equivalent functionality that would minimize the structure's weight and complexity, and probable cost.

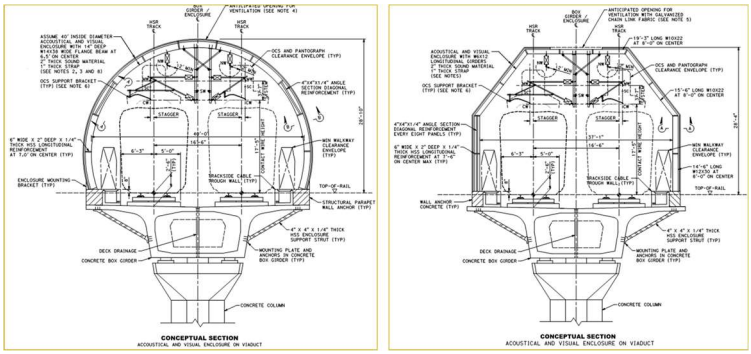

Figure 3: Tubular and Wall Panel Enclosure Concepts

2. Pressure Transient Analysis

A pressure transient (i.e. pneumatic) analysis was necessary to evaluate the impacts of the enclosure on HSR operations at full speed, the impacts to passenger comfort levels, and the impacts the train operation would have on the enclosure. In addition, the operation of a high-speed train within an enclosed space results in a pressure wave in front of and behind the train, that when exiting the enclosed space, would rapidly expand and could generate a loud percussive noise. To ensure the enclosure would not have a detrimental impact on the operation of the train and its surroundings, a preliminary pressure transient analysis was conducted.

The analysis looked at three scenarios: Two trains crossing in the enclosure, a single train passing through the enclosure, and the micro pressure waves at the exit portal. A one-dimensional analysis performed using the ThermoTun-Online software, commonly used for proof of concept, estimated the maximum pressure change to which train passengers and crew are subjected, the maximum/minimum pressures exerted on the enclosure structure, and the magnitude of the pressure wave at the enclosure portals.

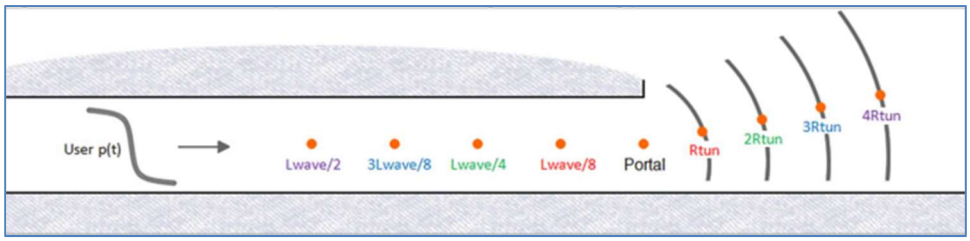

Figure 4: Illustration of the micro pressure waves analysis

To reduce the magnitude of the pressure wave within the enclosure, while minimizing the size of the structure, the designers proposed three openings to be located at the obvert of the enclosure. These openings, each 35% of the enclosure cross-sectional area and spaced out at quarter points along the length of the structure, reduced the estimated maximum pressure by 40% to stay within standard HSR operating parameters.

3. Noise Analysis

A noise analysis was necessary to evaluate the effectiveness of the structure and potential to attenuate noise impacts in the area. The analysis, using Cadna-A modeling software, also evaluated the performance of other structural noise mitigation options including; a noise barrier 14-ft above top of rail (TOR), a 17.5-ft noise barrier, and a 17.5-ft noise barrier with an angled cantilevered top edge (similar to the alternative enclosure concept) to provide a basis for functional comparison.

The acoustical model was used to evaluate the base condition and all four noise mitigation options to allow for direct comparison of results.

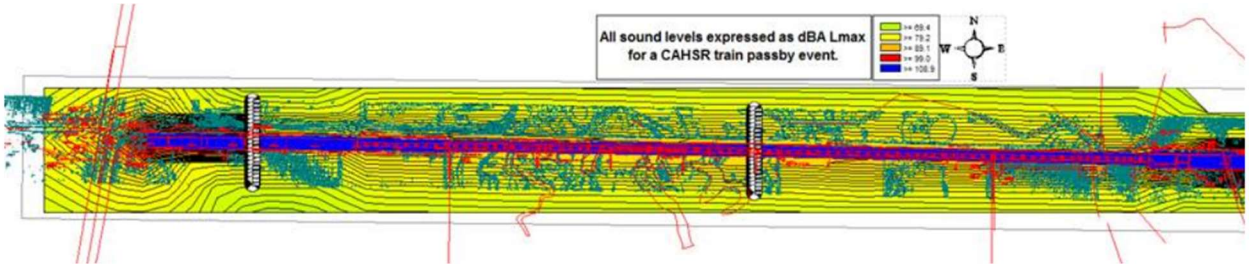

Figure 5: Isopleth Noise Contours

The level of noise reduction increases with the barrier height and extent of enclosure. However, higher levels of noise reduction provided by enclosure come at increasing costs of more complex structures. The results of the analysis showed that the permanent hearing damage criterion (140 dBA Lmax) would not be exceeded. However, temporary hearing damage, masking, and arousal criteria were exceeded and would require additional land based mitigation up to 300-ft from the track alignment.

4. Cost Estimates

A preliminary cost estimate was completed to evaluate the five options under review in the GEA: existing conditions (no mitigation), a noise barrier 14-ft above TOR, a noise barrier 17.5-ft above TOR, a tubular enclosure, and a wall panel enclosure. The cost estimates, supported by material quotes and reviewed by the Authority estimating department, included materials, labor, equipment, and viaduct

structural and foundation improvements. In addition to the capital cost estimates, a rough order of magnitude operations and maintenance (O&M) cost was calculated for the two enclosures as their complexity would result in higher maintenance costs. Land based compensatory mitigation costs were also estimated for each of the structural options. The potential to stack mitigation (i.e. consolidated mitigation for more than a single impact type) enabled an estimated low to high (i.e. separated mitigation for each impact type) range of mitigation costs.

Table 1: Concept level cost estimate

Structure Options	Noise Reduction	Capital Cost	Compensatory Mitigation Cost*	Total ROM Net Cost	ROM Additional O&M Cost (average annual)
None	0 dBA	N/A	$20.5 to 33M	$20.5 to 33M	N/A
Noise Barrier 14-ft>TOR	8 dBA	$36M	$12 to 19M	$48 to 55M	< $60K for 3 miles
Noise Barrier 17.5ft>TOR	10 dBA	$46M	$9.5 to 15M	$55.5 to 61M	
Wall Panel Enclosure	10+ dBA	$90M±	$9.5M to 15M	$100.5M to 106M	≈$60K ± for 3 miles
Tubular Enclosure	12 dBA	$119M	$7M to 11M	$126 to 130M	

*Stacked to Unstacked Mitigation

Conclusions

The results of the analysis showed that the two enclosures would support HSR operations and provide visual and acoustic mitigation at a greater level than a standard noise barrier mitigation measure. In addition, noise barriers lacked the ability to prevent bird strikes, and were therefore eliminated from consideration. The enclosures were deemed conceptually feasible, and due to the sensitivity of resources and stringent regulatory requirements, the Authority is proposing an enclosure as a mitigation measure for regulatory assurance, and technical efficiency. This approach requires further detailed design analysis, and engineering validation that is beyond the scope of preliminary engineering. Language for a proposed mitigation measure has been drafted for the Draft EIR/EIS to assure concept-level feasibility, performance, and efficacy:

- Enclose HSR guideway and OCS continuously for 3.4 miles, centered approximately at Mud Slough. The final recommendation of 3.4 miles is the result of iterative design refinement between engineering and environmental science teams.
- Construct using opaque, nonglare materials that provide a minimum of 10 dBA attenuation of sound generated by HSR operations, as measured immediately outside the enclosure.
- Design in compliance with all HSR design, operations, and maintenance requirements.
- Build in conjunction with installation of track and OCS; completed before HSR train operations begin.

- Consult with CDFW, USFWS, GWD, the owner(s) of private properties affected by the 3.4-mile HSR project footprint, and other stakeholders as part of final design of the guideway enclosure.
- Implement in conjunction with compensatory mitigation, if quantitative modeling of final enclosure design demonstrates residual noise of 77 dBA or more, measured outside the HSR right-of-way.

Pressure Transient Analysis Memo

CALIFORNIA High-Speed Rail Authority

RDP Rail Delivery Partner

DRAFT

Memorandum

DRAFT FOR INTERNAL DISCUSSION ONLY

DATE: April 12, 2019

TO: Julian Bratina

FROM: Silas Li

CC: Brian Sutliff, Steve Klein

SUBJECT: Pressure Transient Analysis for An Acoustic Enclosure

---

Introduction

This memorandum summarizes the pressure transient analysis at conceptual design level for a 3-mile long acoustic enclosure. There is an 0.75 mile approach embankment, then 1.5 mile viaduct over a wetland area, and then another 0.75 mile embankment section that would support the acoustic enclosure structure. The objective of the conceptual design is to verify the cross sectional area of the structure, the size of the proposed obvert openings, and the resulting magnitude of the pressure waves generated by high speed operations. Based on the results of the pressure transient analysis, information will be forwarded to the noise analysis team.

Three scenarios were identified for pressure transient analysis and are discussed below:

1. Two crossing trains in the acoustic enclosure
2. Single train in the acoustic enclosure
3. Micro pressure waves at the exit portal

A 1-dimensional (1D) analysis was performed using the ThermoTun-Online software [1] which is commonly used for proof of concept. The benefit of using 1D model is shorter simulation time. Performing 3D CFD (Computational Fluid Dynamics) analysis would take a few months, and exceed the project schedule of 4 weeks for proof of concept.

The ThermoTun-Online has some limitations. In particular, it cannot simulate 3-dimensional (3D) phenomena in detail and the effects of ceiling openings. It averages values over the tunnel cross-section and estimate these averages vary along the tunnel. The software cannot address multiple ceiling openings. Simulations were performed without ceiling openings. The quantity of openings and size were estimated based on a literature search and engineering judgement.

Assumptions

The following assumptions were made for the pressure transient analysis:

- Cross sections of the acoustic enclosure (tunnel) on viaduct and on embankment (Figures 1 and 2 below).
- Tunnel length = 4,828 m (3 miles)
- Cross-sectional area of tunnel = 88.2 m^2 (950 ft^2)
- Tunnel radius = 4.7 m (15.4 ft)
- Length of train = 400 m (1312 ft)
- Cross-sectional area of train = 11 m^2 (118 ft^2)
- Fanning friction coefficient = 0.008
- Loss coefficient, flow from open tunnel into annulus around train = 0.1
- Shape factor, flow from annulus around train into open tunnel = 0.5
- Speed of train = 354 kph (220 mph)
- Sealing time constant for leakage through coach bodies = 1 second
- Time of nose entry = 0 second (both trains)
- The medical health criteria is taken from TM 2.4.2 for basic high-speed train tunnel configuration.

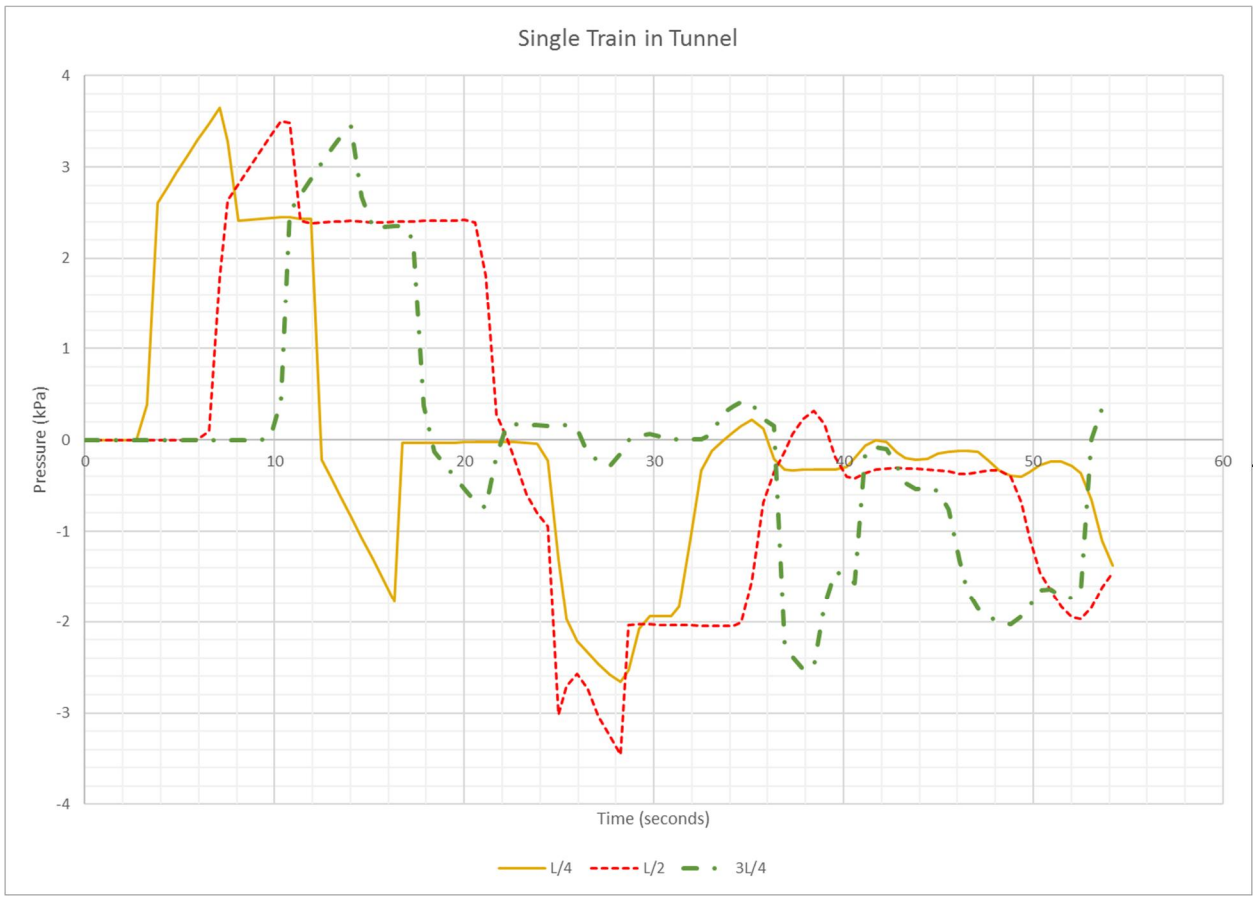

Figure 7: Pressure in the Tunnel

Micro Pressure Waves

Figure 8 below shows the output locations used in Figure 9 showing pressure results.

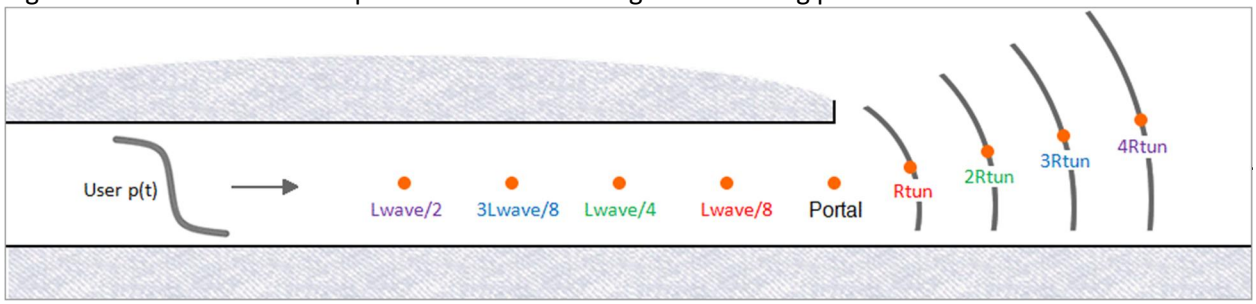

Figure 8: Micro Pressure Waves

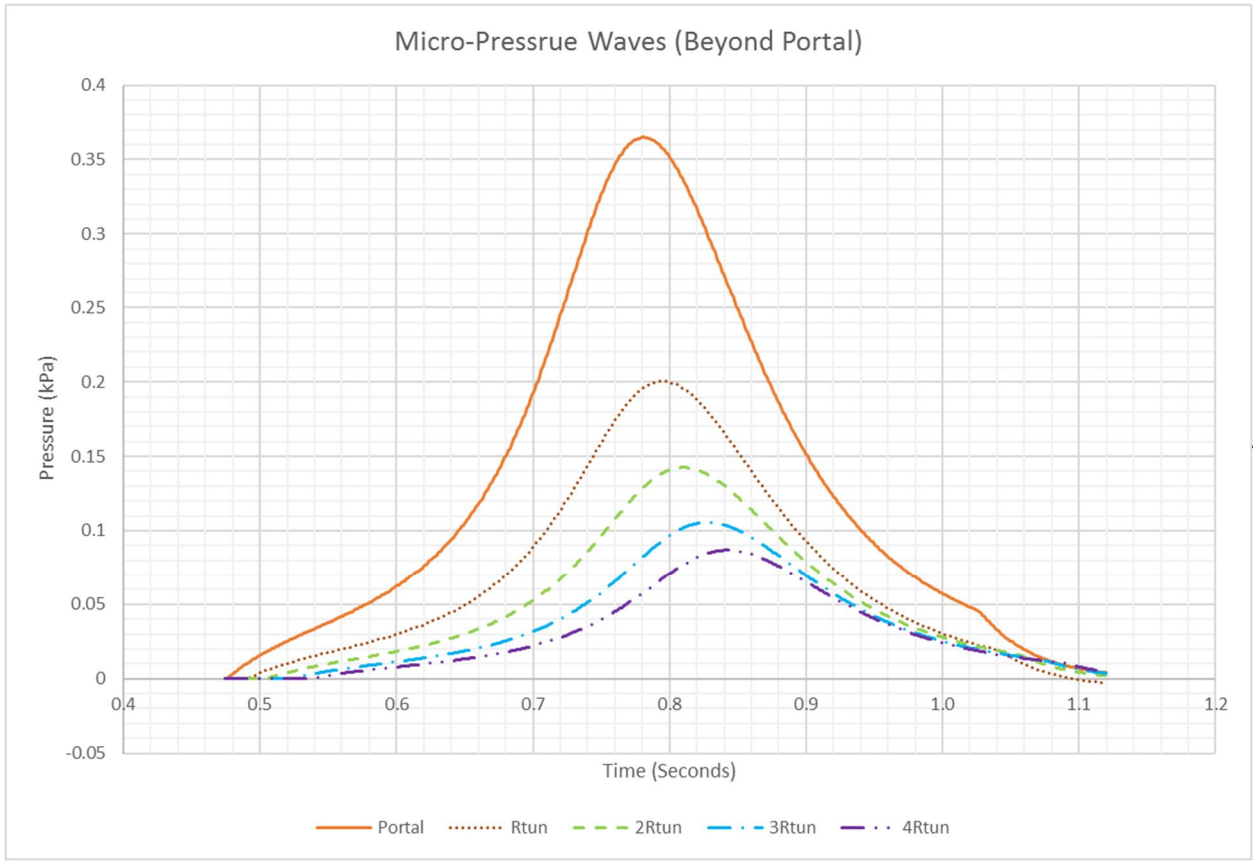

Figure 9: Micro Pressure Waves (Beyond Portal)

Discussions and Conclusions

Preliminary results for Crossing Trains in Tunnel (without Openings):

- Medical health criterion = 10 kPa (peak to peak pressure, Technical Memo TM 2.4.2)
- The maximum pressure change (peak to peak), to which train passengers and crews are subjected, would exceed 14.7 kPa for two trains passing at 354 kph.
- The maximum/minimum pressures on the tunnel structure would exceed +11.0 kPa / -9.8 kPa.

Preliminary results for Single Train in Tunnel (without Openings):

- The maximum pressure change (peak to peak) in the tunnel would be approximately 7.1 kPa.
- The pressure rise when the train entering the tunnel portal is 2.6 kPa.

Preliminary results for Micro-Pressure Waves (without Openings):

- The pressure at the portal is 365 Pa.

Pressure simulations were performed without ceiling openings. The quantity and size of ceiling openings were estimated based on literature search and engineering judgement. Reference [2] suggests that there was little benefit in increasing the number of shafts/openings above three. The cross-sectional area of air shafts/openings in tunnels should be around 10 to 35% of the area of the main tunnel. A total of 3 openings, spaced at approximately 0.75 miles apart could reduce the pressure by up to 40%.

For initial noise analysis, three openings are assumed at 1/4, 1/2 and 3/4 points of the tunnel length. Each opening is assumed to be 35% of the tunnel area or 31 m^2 (334 ft^2). The presence of openings is assumed to reduce the maximum pressure by 40%. This is an estimate for proof of concept at this stage. The tunnels referenced in the literatures are based on particular tunnel configurations, tunnel length, train area and speeds. The initial noise analysis should include two scenarios: 1) higher pressure without openings; and 2) with 3 ceiling openings and 40% reduction in pressure. Detailed analysis, such as CFD and passenger comfort analysis, should be performed for the acoustic enclosure with ceiling openings during next phase of design.

MEMORANDUM

To:	Julian Bratina
From:	Erich Thalheimer
Date:	June 25, 2019
Project Name:	California High-Speed Rail Project
Project Number:	189229H
Subject:	**CAHSR Grasslands Noise Barrier Alternatives Comparison Tech Memo**

Study Overview

This memo summarizes the technical analysis process and results of an acoustical mitigation assessment performed to determine the potential impact of the California High-Speed Rail Project on the Grasslands Ecological Area, and mitigation of such impact. The Grasslands Ecological Area (Grasslands) is home to several species of waterfowl that could be adversely affected by high-speed train noise. Thus, consideration is being given towards reducing the train noise footprint through the rail corridor within the Grasslands.

The proposed alignment runs east and west through the middle of the Grasslands for about 3 miles, from approximately Station 4930 to Station 5085. Parallel noise mitigation barriers on both sides of the tracks have been suggested as an appropriate mitigation technique. Four train noise barrier mitigation designs are considered in this assessment: (1) 14-ft noise barriers, (2) 17.5-ft noise barriers, (3) 17.5-ft noise barriers with a slanted cantilever top edge, and (4) a nearly-complete tunnel enclosure.

The Cadna-A® acoustical model, developed by DataKustik GmbH, was used to perform this study. Cadna-A is a general purpose, three dimensional, ray tracing acoustical model that implements ISO Standard 9613 for outdoor sound prediction and propagation. All four noise barrier alternatives were evaluated using the same Cadna-A model, thus allowing for direct comparison of the results.

This study was not scoped to recommend a preferred alternative. Rather, this study presents an evaluation of the acoustical benefits and consequences of the candidate noise barrier alternatives.

Noise Criteria Thresholds

Several noise criteria thresholds were previously established (by others) for this study to avoid disturbing, upsetting or harming waterfowl residing in the Grasslands area. The noise metric of choice for this study was the maximum sound level (Lmax) measured in A-weighted decibels (dBA) using an RMS 'slow' response time. The justification for this criterion is the desire to avoid startling the waterfowl by the quick onset of noise due to trains moving through the area. Use of the Lmax dBA 'slow' noise metric is consistent with recommendations in the Federal Railroad Administration (FRA) High-Speed Ground Transportation Noise and Vibration Impact Assessment Manual (2012).

The four noise criteria considered and evaluated through this study included the following:

- Permanent hearing damage (Lmax < 140 dBA)
- Temporary hearing damage (Lmax < 93 dBA)
- Avoidance of masking (Lmax < 84 dBA)
- Avoidance of arousal (Lmax < 77 dBA)

As Planned Condition

The current As Planned condition is shown in **Figure 1.** Trains passing through this section would involve CAHSR electric multiple unit (EMU) consists of approximately 660 feet in length, including their locomotives and cars, traveling at about 220 mph. This section of tracks within the Grasslands is relatively straight (east and west) but has a portion of elevated track on a 25-ft high top-of-rail viaduct from Station 4955 to Station 5051. The remainder of the tracks are at grade supported by embankment stone ballast, ranging in top-of-rail heights from 8-ft in the western end to 17-ft in the eastern end. The terrain and topography within 500 feet of both sides of the tracks is quite flat, with elevation changes of less than 10 feet.

Figure 1. Aerial View of CAHSR Grasslands Section

Cadna-A Noise Model

As previously noted, CAHSR train noise levels affecting the adjacent Grasslands were estimated using the Cadna-A® noise model developed by DataKustik GmbH. Cadna-A is a powerful, three dimensional, ray tracing acoustical model that implements ISO Standard 9613 for the prediction and propagation of outdoor sound.

Noise sources are input to the Cadna-A model as point, line and/or area components. Each source is characterized as emitting sound power levels (PWL) in octave bands or broadband A-weighted format. Attenuation due to distance, terrain and elevation differences, ground absorption, wind effects, foliage, building shielding, and attenuation from barriers and berms are computed in the model. The resulting sound pressure levels (SPL) are predicted at any receptor location(s) of interest.

The first step in configuring the Cadna-A model was to import geoshape project design files to serve as a base map of the area. In this manner, the exact alignment of the proposed CAHSR rail corridor could be modeled to a high degree of accuracy, including the topography data inherent in the geoshape files.

The two parallel tracks were then entered into the model at their respective elevations above grade. Cadna-A's optional FRA/FTA module was used in this case to simulate the methods and calculations described in FRA's High-Speed Ground Transportation Noise and Vibration Impact Assessment Manual (2012). The portion of tracks elevated on the viaduct section was assigned to be self-shielding due to the concrete guideway deck, and an adjustment of +3 dB was assigned to the elevated track sections consistent with FRA guidelines. The rest of the surrounding grounds were considered to be moderately acoustically absorptive (G = 0.5) for hard dirt/sand surfaces.

The four noise barrier alternatives were then entered into the Cadna-A model, including: (1) 14-ft noise barriers, (2) 17.5-ft noise barriers, (3) 17.5-ft noise barriers with a slanted cantilever top edge, and (4) a nearly complete tunnel enclose. The surfaces of the barriers facing the trains were assumed to be covered with a material with an average acoustical absorption coefficient of 0.85 NRC in order to reduce the performance degradation effect caused by reflective parallel barriers.

Noise receptors were entered into the model in traverse patterns at three locations, representative of each of the three different track conditions. One location was the approximate center of the track on ballast section towards the west near Station 4942; another location was the approximate middle of the elevated viaduct track near Station 5003; and the final location was the approximate center of the track on ballast section towards the east near Station 5067. The receptors were modeled as being 5 feet above the ground and were positioned in the traverse arrays every 50 feet out to a distance of 500 feet from the tracks (topographical data was not available beyond 500 feet).

Lastly, the noise model computed isopleth contours, or lines of equal loudness, for each of the four noise criteria thresholds (i.e. Lmax = 140, 93, 84 and 77 dBA). In doing so, the results could be presented so that the four respective noise impact zones (or noise criteria exceedance zones) can be clearly seen relative to one another.

Noise Barrier Results

The noise impact zones, or isopleth contour lines, for the As Planned (i.e. without barriers) and for the four noise barrier alternatives are shown in **Figures 2 thru 11**. Two figures, a western half and an eastern half, are provided for each scenario.

The results indicate that concern for permanent hearing damage (i.e. Lmax = 140 dBA) was unwarranted. The impact zone for 140 dBA would occur too close to the train itself to warrant any further concern. Therefore, each of the figures only shows isopleth lines for Lmax = 93, 84 and 77 dBA, respectively.

To be effective, a noise barrier must, at a minimum, break the line-of-sight between the noise source and the receptor. Noise barriers need to be very long relative to their height to avoid noise from flanking around the endpoints. In this manner, the height of the barrier becomes the most important aspect in determining its noise reduction effectiveness. The taller a noise barrier, the more noise reduction it will provide for receptors on the other side. The position of the barriers, relative to the noise source, was limited in this case to being erected along the CAHSR right-of-way (ROW).

As expected, the size of the noise impact zones gets smaller with each more substantial noise barrier alternative. Thus, the noise reduction provided by the 14-ft barrier is greater than the As Planned condition; the noise reduction provided by the 17.5-ft barrier is greater than the 14-ft barrier; the noise reduction provided by the 17.5-ft cantilever barrier is greater than the 17.5-ft barrier; and the noise reduction provided by the tunnel barrier is greater than the 17.5-ft cantilever barrier.

Table 1 summarizes the Cadna-A noise model results for the three traverse lines of discrete receptors (i.e. Western, Middle and Eastern). While the impact zone distances vary somewhat from point to point, the results in the table give an overview of the noise reduction benefits associated with each barrier alternative. The results in the table are approximations, rounded to nearest 50-ft increment. More exact definition of the noise impacts zones should be taken from the isopleth contour lines in **Figures 2 thru 11**.

Table 1. CAHSR Grasslands Noise Impact Zones and Noise Barrier Effectiveness

Design Scenario	**Approximate Noise Impact Zones (Feet From Tracks)**											
Track Segment	**Western**				**Middle**				**Eastern**			
Stations	Sta. 4930 to Sta. 4955				Sta. 4955 to Sta. 5051				Sta. 5051 to Sta. 5085			
Track Condition	Ballast TOR = 8 ft				Elevated TOR = 25 ft				Ballast TOR = 17 ft			
Noise Criteria	Perm	Temp	Mask	Arouse	Perm	Temp	Mask	Arouse	Perm	Temp	Mask	Arouse
As Planned	0	250	>500	>500	0	50	>500	>500	0	200	>500	>500
14 ft Barriers	0	<100	150	>500	0	<50	150	>500	0	<100	100	500
17.5 ft Barriers	0	<100	100	450	0	<50	150	>500	0	<100	100	400
17.5 ft Cantilever Barriers	0	<100	100	400	0	<50	150	500	0	<100	100	400
Tunnel Barriers	0	<100	100	300	0	<50	150	450	0	<100	100	300

Notes: Perm = Permanent hearing damage (Lmax < 140 dBA)
Temp = Temporary hearing damage (Lmax < 93 dBA)
Mask = Avoidance of masking (Lmax < 84 dBA)
Arouse = Avoidance of arousal (Lmax < 77 dBA)

As can be seen in the table, the provision of even a 14 ft tall barrier will provide significant noise reduction compared to the As Planned condition. The installation of taller or more comprehensive barriers would further reduce noise levels affecting the Grasslands, but at a less significant incremental rate, meaning there are diminishing returns for the additional costs involved with building larger barriers.

It is hoped that this study will aid CAHSR officials in considering these noise barrier alternatives from a quantitative perspective. Refinements to these noise barrier alternatives, or additional noise analyses are available upon request.

Disclaimer – This study only examined the acoustical aspects of the subject noise barriers. No attempt was made to estimate the costs of the barriers, or the structural requirements to build the barriers.

APPENDIX 3.7-D: SUPPLEMENTAL SPECIES HABITAT MODEL DESCRIPTIONS

Monarch butterfly (*Danaus plexippus*); Candidate under the FESA

Modeled Habitat Categories and Modeling Parameters	Model Evaluation
The monarch butterfly occurs throughout the United States and southern Canada where milkweed species (*Asclepias* spp.), their host plants, are present (Pelton et al. 2016; Western Association of Fish and Wildlife Agencies 2019). Breeding habitat contains native milkweeds to provide food for larvae and other flowers to provide nectar for adults but may also include trees or shrubs for shading and roosting and connectivity among these habitat elements. During the spring and summer, adult monarch butterfly spends its 2- to 5-week lifespan mating and nectaring on flowers, with the females searching for milkweed upon which to lay their eggs. Multiple generations are produced over the fall and summer, with the fall generation of adults migrating to overwintering sites and living for 6 to 9 months until the next spring breeding season (Pelton et al. 2016). The western monarch butterfly population breeds west of the Rocky Mountains and largely overwinters in coastal California, while the much larger eastern populations breed east of the Rocky Mountains and overwinter in Mexico (Western Association of Fish and Wildlife Agencies 2019). Monarch butterfly habitat is often described in terms of breeding, migratory, and overwintering sites. Breeding habitat contains native milkweed and other flowers to provide food for larvae and nectar for adults and trees or shrubs for shade and perching (Pelton et al. 2016 Xerces Society for Invertebrate Conservation 2018). There are 15 species of native milkweed is California, which occur in a variety of different habitats (Xerces Society for Invertebrate Conservation 2018), although nine species are rare and restricted in range and distribution (Xerces Society for Invertebrate Conservation 2011). Migratory habitat consists of nectar plants for adults during spring and fall migration. Breeding and migratory habitat are often synonymous since they contain the same key components (i.e., milkweed, nectar sources, roosting structures) (Western Association of Fish and Wildlife Agencies 2019). Overwintering sites in California are found in selected forested areas generally located within 1.5 miles from the Pacific Ocean or San Francisco Bay (Leong et al. 2004). Most overwintering sites occur at low elevations (<300 feet), in shallow canyons (Lane 1993), and on south-, southwest-, or west-facing slopes to maximize solar radiation and shelter from wind (Leong et al. 2004). Suitable grove conditions include temperatures above freezing, high humidity, dappled sunlight, access to water and nectar, and protection from high winds and storms (Western Association of Fish and Wildlife Agencies 2019). Trees commonly used for roosting in California include blue gum eucalyptus, Monterey pine, and Monterey cypress, but clusters have also been observed on red gum eucalyptus, western sycamore, coast redwood, coast live oak, Fremont's cottonwood, and Goodding's willow (Pelton et al. 2016; Western Association of Fish and Wildlife Agencies 2019). The California Natural Diversity Database (CNDDB) (CDFW 2020) and the Western Monarch Count (Xerces Society for Invertebrate Conservation 2020) does not identify any overwintering sites in the regional study area. The Western Monarch Count displays data from the Xerces Society's Western Monarch Overwintering Sites Database, which contains 400+ overwintering sites from records stretching back to 1970. The database includes historical records, original site surveys as part of the annual Western Monarch Thanksgiving Count (WMTC), and focused survey efforts by Xerces staff. The majority of known large overwintering sites are included in the WMTC to allow comparisons between years and sites and provide an estimate of the size of the monarch population that overwinters in western North America (Pelton et al. 2016). Records of milkweed, adult monarch butterflies, and breeding activity are prevalent throughout the study area (Xerces Society for Invertebrate Conservation 2018).	Prior to distribution for review by agency biologists, California High-Speed Rail Authority biologists knowledgeable about this species evaluated the model results and compared all habitat model types to the distribution of all occurrences in the CNDDB and Western Monarch Count (CDFW 2020; Xerces Society for Invertebrate Conservation 2020).

Modeled Habitat Categories and Modeling Parameters	Model Evaluation
Breeding/Migration Habitat—Potentially suitable breeding/migration habitat in the regional study area meets the following criteria (see Figure 3.7-D-1). ▪ Current range (Pelton et al. 2016; Western Association of Fish and Wildlife Agencies 2019) ▪ The following land cover types coincide with the habitat for milkweed (Xerces Society for Invertebrate Conservation 2011, 2018): all herbaceous-dominated land cover types, all tree-dominated land cover types, all aquatic land cover types, all agricultural land cover types, rock outcrop, constructed basin, and constructed watercourse.

NOVEMBER 2020

Figure 3.7-D-1 Monarch Butterfly Habitat

Mountain lion (*Puma concolor*); Candidate under the CESA (Southern California/Central Coast Evolutionarily Significant Unit)

Modeled Habitat Categories and Modeling Parameters	Model Evaluation
Mountain lions occur broadly throughout the United States. In California, mountain lions occur in nearly all habitats (Zeiner et al. 1990). They require large areas of relatively undisturbed habitats with adequate connectivity to allow for dispersal and gene flow for population persistence (Center for Biological Diversity 2019). Wilmers et al. (2013) found that mountain lions were generally attracted to shrub, forest, and water; they were deterred by grasslands. Although this study shows that tree- and shrub-dominated habitat types are preferred over grasslands and human-disturbed areas during the day, nocturnal movement patterns showed that mountain lions utilize a broader range of habitats as they travel through their home ranges and hunt (Dickson et al. 2005; Wilmers et al. 2013). Mountain lions tend to avoid intensively developed suburban or urban areas, especially for denning and breeding (Dickson and Beier 2002; Wilmers et al. 2013). Dens are located in rocky terrain or in dense vegetation that provides cover (Zeiner et al. 1990; Wilmers et al. 2013). In June 2019, the Southern California/Central Coast evolutionarily significant unit (ESU) of mountain lion was petitioned for listing under the California Endangered Species Act (CESA). The California Department of Fish and Wildlife evaluated the petition, and the California Fish and Game Commission published a notice of findings on May 1, 2020, to list the Southern California/Central Coast population ESU as a candidate for listing under CESA. Six subpopulations comprise the ESU: (1) Santa Ana Mountains, (2) Eastern Peninsular Range, (3) San Gabriel/San Bernardino Mountains, (4) Central Coast South (Santa Monica Mountains), (5) Central Coast North (Santa Cruz Mountains), and (6) Central Coast Central. The boundaries of the ESU include areas generally south of the San Francisco Bay and Interstate (I-) 80, west of I-5 to the intersection of I-5 and State Route (SR) 58, south of SR 58 to I-15, south of I-15 from the SR 58 intersection to the California-Nevada border, and south to the California-Mexico border. The mountain lion habitat distribution model includes all areas of suitable habitat regardless of ESU (the majority of the study area is within the ESU); however, only animals within the ESU are candidates for listing under CESA. The mountain lion habitat distribution model is based on the assumption, as presented in both Burdett et al. (2010) and Wilmers et al. (2013), that anthropogenic factors modify mountain lion habitat suitability. Wilmers et al. (2013) found that human development has a stronger habitat selection pressure on denning behavior than nonreproductive behaviors, thus requiring a large setback from human development for breeding habitat. Furthermore, Wilmers et al. (2013) also found that mountain lions were more deterred by human development that provides more varied sources of human interferences (i.e., residences would be more strongly avoided than arterial roads) and give those areas a wider berth. Although mountain lions will use moderately disturbed areas as they travel and hunt (Wilmers et al. 2013; Gray et al. 2016), occupancy is lower in developed areas, and they are more likely to use developed areas if they border open spaces (Wilmers et al. 2013; Wang et al. 2015). Thus, mountain lions require a habitat mosaic that provides sufficient distance from human-disturbed areas for breeding and is connected to expansive, intact, heterogeneous habitats (Dickson and Beier 2002; Dickson et al. 2005; Kertson et al. 2011; Zeller et al. 2017). Wilmers et al. (2013) found that the influence of housing density on movement behavior was most effective when based on density of the surrounding area out to a distance of 150 meters and likewise on denning behavior based on a density calculated from a 600-meter search. ***Breeding and Foraging Habitat —***Potentially suitable breeding and foraging habitat in the regional study area meets the following criteria (Figure 3.7-D-2).	Prior to distribution for review by agency biologists, California High-Speed Rail Authority biologists knowledgeable about this species evaluated the model results. In response to the review, the rationale, model names, and the description of how the Wilmers et al. (2013) data was used to inform the breeding and foraging habitat model were revised for clarity.

Modeled Habitat Categories and Modeling Parameters	Model Evaluation
▪ Current range (Zeiner et al. 1990) AND ▪ All tree-dominated and shrub-dominated natural landcover types (Authority 2016) AND ▪ Areas having a dwelling density (within Santa Clara County only) less than 0.04 units per acres[1]	
High-Priority Foraging and Dispersal Habitat—High-priority foraging and dispersal habitat in the regional study area meets the following criteria (Figure 3.7-D-2). ▪ Current range (Zeiner et al. 1990) AND ▪ All herbaceous, shrub, woodland, and forested natural land cover types (Authority 2016) AND ▪ Within areas of high movement value[2] AND ▪ Does not meet the conditions of breeding and foraging habitat (as defined in the above model description).	

[1] Dwelling density is calculated using address points acquired from Santa Clara County. Density is calculated within a radius of 600 meters (1,968 feet) consistent with Wilmers et al. (2013). Within the regional study area and the species range, for the purposes of this analysis, it is assumed that dwelling density is only high enough to alter breeding habitat within Santa Clara County. For the portions of the regional study area outside Santa Clara County, dwelling density is assumed to be sufficiently low such that all suitable land cover types will be considered breeding habitat.

[2] Movement values were calculated as inputs to the local permeability modeling performed under the *Wildlife Corridor Assessment Report* (Authority 2020, Appendix C) in which landscape permeability is based on a calculated Habitat Suitability Index (HSI), which is a function of ranked land cover, road density, and topographic conditions. Areas having an HSI value higher than 50 (1–100 scale) (i.e., higher score indicated a greater potential for use as a movement corridor) were included in the high-priority foraging and dispersal habitat model.

Modeled Habitat Categories and Modeling Parameters	Model Evaluation
Low-Priority Foraging and Dispersal Habitat—Low-priority foraging and dispersal habitat in the regional study area meets the following criteria (Figure 3.7-D-2). ▪ Current range (Zeiner et al. 1990) AND ▪ All herbaceous, shrub, woodland, and forested natural land cover types (Authority 2016) AND ▪ Within areas of low movement value[3] AND Does not meet the conditions of breeding and foraging habitat (as defined in the above model description).

NOVEMBER 2020

Figure 3.7-D-2 Coastal Mountain Lion Habitat

APPENDIX 3.7-E: SUPPLEMENTAL NOISE ANALYSIS ON TERRESTRIAL WILDLIFE SPECIES

1 INTRODUCTION

Noise is defined as undesirable sound. Thus, the analysis of noise effects relies upon the theory and methods of acoustics, as applied to sensitive resources. Those resources include terrestrial wildlife in the study area: amphibians, reptiles, birds, and mammals. Acoustic concepts relevant to this analysis are presented in the *Wildlife Corridor Assessment Report* (WCA) (Authority 2020, Appendix C, Section 4.5.3.1).

All native wildlife potentially present in the project area were considered as potentially vulnerable to noise effects; however, this analysis is focused on mammals for the following reasons:

- An analysis of noise effects on birds has been presented in the WCA (Authority 2020, Appendix C, Sections 4.5 and 6.2.1.2).
- Reptiles and amphibians have very limited sensitivity to sound but appreciable sensitivity to vibration; thus, high-speed rail (HSR) impacts via that mechanism are more substantial. The Final environmental impact report (EIR)/environmental impact statement (EIS) will present an analysis of reptile and amphibian susceptibility to vibration.
- No evidence suggests invertebrate sensitivity to noise.
- The WCA (Section 6.2.1.1) analyzed noise effects on mammals in an analysis that relied mainly upon guidance propagated for evaluating noise effects on livestock. In response to public comment, this analysis more closely examines mammalian responses to HSR noise sources.

Analysis of mammalian wildlife response to noise generated by HSR traffic relies upon considerations of exposure and response. Exposure describes the noise itself, and response describes how the noise affects the animal. Existing studies of HSR noise and existing baseline noise sources, along with acoustic models, permit a quantitative estimation of noise exposure. Response, however, generally cannot be described in quantitative terms and must be inferred from published studies that consider different noise sources, different animals, and different locations compared to those that occur in the study area.

In this analysis, impacts of noise on mammalian wildlife are described as significant if either of the following California Environmental Quality Act (CEQA) significance thresholds would be exceeded:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife (CDFW) or U.S. Fish and Wildlife Service (USFWS)
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites

The Council on Environmental Quality (CEQ) National Environmental Policy Act (NEPA) regulations (40 C.F.R. Parts 1500–1508) provide the basis for evaluating project impacts (as described in Section 3.1.6.4, Methods for Evaluating Impacts, of the Final EIR/EIS). As described in Section 1508.27 of these regulations, the criteria of context and intensity are considered together when determining the severity of the change introduced by the project.

- **Context—**For the analysis of impacts on biological and aquatic resources, the context would be the existing resources within the resource study area (RSA): the status of sensitive communities and species that occur or that could occur along the project corridor and the regulatory setting pertaining to biological and aquatic resources.
- **Intensity—**For the analysis of impacts on biological and aquatic resources, the intensity or severity of an impact would reflect the magnitude of the change between the existing and projected conditions—specifically, the degree to which the construction and operations of the project could affect these resources.

2 NOISE EXPOSURE IN THE STUDY AREA

Exposure has many components, such as:

- The timing and duration of the noise
- The distribution of noise energy at different frequencies
- How loud the noise is at different distances from the rail line
- How loud it is relative to background noise levels from other sources such as highways and airports

Existing studies of HSR noise and background noise, as well as acoustic models, permit a quantitative estimation of noise exposure. Much of this information is summarized in WCA Section 4.5.3.1 (Authority 2020, Appendix C), which describes how loud the train would be, how much acoustic energy would be generated at different frequencies, how noise is generated by a passing train, and the methods used to model noise generation. That analysis is focused on trains moving through rural areas associated with the Pajaro River Important Bird Area (IBA) and the Grasslands Ecological Area IBA, areas in which trains would achieve speeds of 220 miles per hour (mph). Terrestrial wildlife would also be exposed to train noise in areas between San Jose and the Pajaro River IBA, where trains would generally be moving more slowly and producing less noise, although taking longer to pass any stationary receptor. This analysis conservatively assumes that such trains would produce the same noise as the trains moving at a higher speed but would take twice as long to pass any affected animals.[1] The WCA also presents maps (Authority 2020, Appendix C, Figures 6-1, 6-2, and 6-3) showing the results of noise modeling for trains passing through the Upper Pajaro River IBA and the Grasslands Ecological Area IBA. Outside of those two areas, this analysis assumes peak noise levels consistent with that model. Although this introduces uncertainty to the analysis, it is a conservative assumption that the train is producing the same amount of noise as if it were traveling at 220 mph. The noise levels generated by such a train are shown in Table 1.

Table 1 Modeled Unshielded Distance to L_{max} Noise Contour for a Train Moving at 220 mph

L_{max}	Rail Alignment Type	
	Aerial (feet)	Embankment (feet)
93 dBA	93	138
87 dBA	278	320
81 dBA	555	760
75 dBA	1,100	1,580
69 dBA	2,200	3,180
63 dBA	4,400	6,350
57 dBA	8,800	12,700
51 dBA	17,600	25,400
45 dBA	35,200	50,800
39 dBA	70,400	101,600

dBA = A-weighted decibel
L_{max} = maximum sound level
All distance estimates are subject to acoustic model assumptions of flat terrain, agricultural vegetation, and no wind. Actual distances would be expected to vary depending on local conditions of train speed, wind speed and direction, air temperature, humidity, topography, buildings, and vegetation cover.

[1] Projected train speeds in this area vary between the alternatives but fall within the range of 110 to 220 mph.

It is assumed that a typical train would be 660 feet long and that approximately 176 trains would pass any given point in any given 24-hour period, with up to 148 trains between 7 a.m. and 10 p.m. and up to 28 trains between 10 p.m. and 7 a.m. A train moving past a given point would take 2.05 seconds to pass at a speed of 220 mph or 4.10 seconds at 110 mph; thus, maximum noise levels would be experienced for 5.8 minutes per day along parts of the alignment where trains were moving 220 mph or 11.6 minutes per day where trains were moving 110 mph. Train noise is also propagated forward and backward along the track, so lower noise levels would be experienced for longer durations.

Trains would sound horns when approaching stations and also at certain crossings. Horns would not be sounded for grade crossings under Alternatives 1, 2, or 3 but would be sounded under Alternative 4. All proposed locations for sounding of horns coincide with locations where horns are currently sounded by Caltrain or freight trains. Federal Railroad Administration (FRA) requirements for locomotive horns are summarized in Section 3.1.3.3 of the *Noise and Vibration Technical Report* (Volume 2, Appendix 3.4-A). The minimum permissible sound level for a horn is 96 dBA at a distance of 100 feet, and this is the proposed level under the project. Although the horns point forward, field measurements indicate that horns are approximately omnidirectional. Due to the rapid onset rate of horn noise, it has a high potential to cause a startle or stress response in affected wildlife. L_{max} values for horn noise would be perceived at distances approximately 50% greater than the values shown in Table 1. Nearly all horn-sounding locations are in urban areas that provide little value for wildlife, but four locations are within the rural area between the San Jose and Morgan Hill urban areas, and two are within the first mile south from the Gilroy urban area.

Existing background noise levels in the study area are presented in Appendix B of the *Noise and Vibration Technical Report* (Volume 2, Appendix 3.4-A). As shown there, L_{90} noise levels (i.e., the noise level that is exceeded 90% of the time, roughly an indication of the most quiet time of the day) from San Jose through Gilroy range from approximately 35 to 70 dBA. One station, N132, was located in the biologically sensitive upper Pacheco Creek area, and this station recorded an L_{90} noise level of 33 to 72 dBA. In the Upper Pajaro River IBA, measurement site N130 found an L_{90} noise level of 30 to 49 dBA. In the Grasslands Ecological Area IBA, L_{90} noise levels of 30 to 70 dBA were found at measurement sites N134, N135, and N136. Most stations show minimum levels between midnight and 5 a.m., and two periods with maximum levels at about 7 a.m. and 6 p.m.

Along much of the alignment, noise exposures would be reduced due to masking effects or due to mitigation in the form of noise barriers. Masking is defined as reduced perception of one sound due to the introduction of another sound. In this case, noise produced by an HSR train may be masked by the presence of another, louder noise source such as a highway or non-HSR railway. These factors are difficult to quantify. Masking effects would occur in areas where a competing noise source (vehicular traffic, usually associated with a major highway or an urban core area) would mask the noise of the HSR trains. Masking effects would be variable due to variation in the noise level produced by the masking source, as well as variation in the HSR noise levels. In general, though, the times of day with heavy HSR traffic coincide with the times of day having heavy vehicular traffic, and light HSR traffic tends to coincide with light vehicular traffic. Thus, masking would reduce the effects of HSR noise during the hours of peak activity, while having relatively little effect on HSR noise during the late night and early morning hours of minimum traffic.

The principal masking noise sources are highways and urban areas. The entire alignment north of Station B665+00 is located in the San Jose urban area. In this area, there are numerous arterial roads that support traffic much of the day, and the alignment is also collocated with Caltrain and freight rail traffic. Thus, noise impacts from the project would be masked on both sides of the alignment through much of the day. Southwards, to approximately Station B1025+00, the project is still collocated with Caltrain and freight rail. Immediately to the east is arterial traffic on Monterey Road, and approximately 1 mile farther east is U.S. Highway 101, a major freeway. Thus, noise impacts are partially masked between the alignment and Coyote Creek and are substantially masked east of U.S. Highway 101; however, there are few and minor masking

features west of the alignment, except that some topographic masking would occur in areas west of the valley floor. Continuing south, urban area masking would occur through the cities of Morgan Hill and Gilroy, down to Station B1730+00 where the rail alignment intersects U.S. Highway 101. South of there, however, the line turns east and transits open agricultural lands across the valley floor to about Station B2250+00; throughout this area, there are no major sources of masking noise on the landscape. Eastward to Station B2350+00, the alignment crosses State Route (SR) 152, then passes through a tunnel, and then crosses SR 152 again. The busy highway would provide some masking effect to reduce noise effects in the hills north of SR 152, while the tunnel would mask all train noise. From Station B2350+00 to B3330+00, the alignment would follow the valley of Pacheco Creek. Throughout this area, SR 152 is never more than 0.5 mile north of the alignment, and it would provide substantial masking in that direction. To the south, however, there are no sources of masking noise, except that some topographic masking would occur in areas on the slopes west of Pacheco Peak. From Station B3330+00 to Station B4030+00, the alignment is in a tunnel, and noise effects on wildlife would not be a concern. East from there to Volta, Station B4630+00, the alignment traverses rural and agricultural lands, with little masking except locally where the alignment crosses Interstate (I-)5 at nearly a perpendicular angle. From Volta to the project's eastern limit at Station B5330+00, however, the alignment traverses agricultural and wildlife lands on the south side of Henry Miller Road, a moderately busy arterial, which provides some masking for lands north of the alignment but no masking for lands south of the alignment. These masking features are summarized in Table 2, and the areas identified in Table 2 are shown in Figure 1.

The Final EIR/EIS proposed mitigation features to reduce noise impacts on humans and birds. These features in most locations consist of noise barriers, approximately 14 to 17 feet high, erected on both sides of the alignment. These noise barriers would attenuate noise by an average of 10 dBA for an observer located 100 feet from the alignment, with greater effect at lesser distances and reduced effect at greater distances. At greater distances, the attenuation effect is reduced due to reflection and refraction effects on sound waves emerging from between the barrier walls. Noise barriers are proposed in areas having sensitive human receptors (in accordance with the analysis in Section 3.4, Noise and Vibration, of the Final EIR/EIS) and within the Pajaro River and Grasslands Ecological Area IBAs (as specified in Section 3.7, BIO-MM#80, Minimize Permanent Intermittent Noise, Visual, and Train Strike Impacts on Wildlife Movement, of the Final EIR/EIS). Noise barriers protecting sensitive human receptors are predominantly located in urban areas, where they offer little benefit for wildlife. The locations of noise barriers proposed to protect wildlife, however, are listed in Table 2. In these areas, the noise exposure distances shown in Table 1 would be reduced by approximately two-thirds, with a smaller reduction (approximately one-third) for distances greater than about 5,000 feet.

[1] Stationing shown is for Alternatives 1, 2, and 4. Under Alternative 3, the noise barrier would extend from Stations B1870 to B2097. Also, Alternative 3 would avoid the Gilroy urban area but instead would experience masking from U.S. Highway 101 from there to the maintenance-of-way facility (MOWF).
[2] There would be some local masking where the rail alignment crosses Interstate 5. The extent of masking would vary with conditions but would likely be within 1,000 feet of the highway more than 90% of the time.

3 MAMMALIAN WILDLIFE RESPONSES TO NOISE

Mammalian wildlife use sound mainly to forage, to evade predators, and for intraspecific communication. Among wildlife, hearing is arguably the most important sense; secondary loss of vision is more common than loss of hearing (Fong et al. 1995), suggesting that an animal with impaired hearing is at greater risk than one with impaired vision. Hearing enables herbivores to continue foraging while they listen for evidence of an approaching predator. Hearing enables predators to be effective in situations where vision has limited usefulness, such as dense vegetation or darkness. Many species of mammalian wildlife can hear sounds inaudible to humans. Whereas humans can hear sounds at frequencies of approximately 64 to 23,000 Hertz (Hz), most wild mammals can hear higher frequencies, with some bats hearing frequencies of 110,000 Hz, and some mammals hearing lower frequencies, e.g., 16 Hz in ferrets (Strain 2020). Hearing sensitivity in mammalian wildlife is generally comparable to that of humans, with a peak sensitivity of approximately 0 decibels (dB) recorded in such diverse mammals as ungulates, rodents, and bats (Heffner and Heffner 2010; Dent et al. 2018). However, predators often have considerably more sensitive hearing. The most sensitive species studied, the red fox, can hear sounds at -15 dB at 4 kilohertz (kHz), and the raccoon can hear to -12 dB at 1 kHz (Malkemper et al. 2014). That corresponds to sounds one-quarter to one-fifth as loud as the softest sound audible to a human. Reptiles, in comparison, have very poor hearing, with thresholds of 40 dB or greater and almost no ability to hear outside of a frequency range from ca. 50 to 1,000 Hz (Bowles 1995; Young and Aguilar 2002).

Francis and Barber (2013) describe noise effects on wildlife as ranging along a continuum from infrequent, abrupt, and unpredictable noise to chronic noise. The former noise may constitute a disturbance that elicits an antipredator response (Frid and Dill 2002; Francis and Barber 2013). Such a response is often called “startle” but can include a variety of antipredation responses such as vigilance and flight. Antipredation responses can affect mammalian wildlife by masking acoustic information (Francis and Barber 2013).

Masking is defined as reduced perception of one sound due to the introduction of another sound. In this case, wildlife perception of important sounds such as the activity of predators or prey may be masked by the sound of a passing HSR train. There have been extensive studies of masking effects in wildlife; a thorough review by Barber et al. (2010) provides the following examples, which give evidence of the diversity of mammalian wildlife reliance on sound:

- Proximity to noise sources increases vigilance behavior by California ground squirrels, at a cost to foraging efficiency.
- Pronghorn spend more time being vigilant and less time foraging within 300 meters of a road.
- For bats, frequencies between approximately 3 and 8 kHz are crucial for accurate sound localization.

There is evidence that noise of the magnitudes and durations that would occur under the project can elicit an antipredation response in mammalian wildlife. Train noise is not expected to exceed 93 dBA (L_{max}) at 138 feet (Table 1),[2] and, as discussed earlier, exposure to noise of this intensity would last no more than a few seconds at a time. However, due to the high speed of the train, onset levels would be rapid and thus could elicit an antipredation response. One study has found that sound levels above about 90 dB are likely to be adverse to mammalian wildlife and are associated with behavioral responses such as retreat from the sound source, freezing, or a strong startle response, but sound levels below about 90 dB usually do not cause such responses (Manci et al. 1988). However, more recent studies addressing a variety of wildlife species have not set quantitative thresholds of effect and have emphasized that a noise does not necessarily have to be at high intensity to elicit an antipredation response. In particular, temporal and spatial

[2] Alternatively, 96 dBA L_{max} at 100 feet when a train horn is being sounded. This is approximately the same noise level as 93 dBA at 138 feet, but few horn-sounding locations occur in modeled wildlife habitat. 96 dBA at 100 feet is also the peak noise level experienced under current conditions in portions of the proposed alignment colocated with Caltrain or freight train tracks.

context and similarity to relevant biological sounds are also important (Shannon et al. 2016). A study of desert bighorn and mule deer response to simulated military aircraft noise found that for exposures of one to seven simulated flybys per day, broadcast through loudspeakers at noise levels of 92 to 112 dB (i.e., levels comparable to or up to 10 times louder than the HSR train), animal responses included elevated heart rates for up to 3 minutes and sometimes looking toward the sound. Flight or evasion was not observed, and habituation to repeated exposures was observed. At the lowest noise levels, i.e., 92 dB, these responses were minimal (Weisenberger et al. 1996). Conversely, a study of pronghorn near highways in Alberta found that busy roadways (defined as more than 300 vehicles per day) were associated with elevated levels of vigilance and reduced foraging activity levels for pronghorn near the roadway (Gavin and Komers 2006). Accordingly, there is a substantial potential for train passage to produce an antipredation response in wildlife near the tracks, but data are insufficient to state the area within which such a response may occur in any given wildlife species. Antipredation response, whether triggered by noise or other stimuli, has been associated with a wide variety of responses in mammalian wildlife, including reduced foraging efficiency, altered mating behavior, reduced care for young, flight, stress physiology, and increased bioenergetic costs, with potential consequences both for individual fitness and for wildlife populations (Frid and Dill 2002; Francis and Barber 2013).

It is also possible that noise may affect wildlife movement corridors by deterring mammalian wildlife from crossing the rail alignment. A variety of studies have been performed to evaluate wildlife tendencies to cross barriers, usually major highways. In the Coyote Valley area, the *Coyote Valley Linkage Assessment Study* (Pathways for Wildlife et al. 2016) found that “Wildlife, including bobcat, grey fox, coyote, deer and other small and medium-sized mammals have been documented traveling from Coyote Ridge and Coyote Creek County Park on the east side of Coyote Valley by using the Coyote Creek Golf Course Drive Underpass to safely cross underneath Highway 101.” It also notes that roadkill provides evidence of mountain lion and badger attempts to cross U.S. Highway 101. Further camera trapping efforts documented by *Safe Passage for Coyote Valley* (Phillips et al. 2012) show crossing below U.S. Highway 101 in Coyote Valley by a mountain lion and a dusky woodrat. In the western Pacheco Pass area, recent camera trapping efforts at bridges along SR 152 by Pathways for Wildlife (2020) found that “within the twelve month monitoring period, multiple species including deer (*Odocoileus hemionus*), American badger (*Taxidea taxus*), coyote (*Canis latrans*), bobcat (*Lynx rufus*), gray fox (*Urocyon cinereoargenteus*), raccoon (*Procyon lotor*), striped skunk (*Mephitis mephitis*), and opossum (*Didelphis virginiana*) were recorded consistently traveling under each of the three bridges.” Based on this evidence, it is clear that despite the presence of existing noise sources in the form of major highways, both common and sensitive wildlife do successfully use existing passage routes in the study area.

4 IMPACT ASSESSMENT

A substantial impact would occur if the project would have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFW or USFWS. Eleven special-status mammal species are potentially affected: San Joaquin kit fox, Fresno kangaroo rat, mountain lion, Tule elk, badger, dusky-footed woodrat, ringtail, Townsend’s big-eared bat, western mastiff bat, pallid bat, and western red bat.

Noise has been identified as potentially affecting any of these species through behavioral changes such as masking prey sounds, masking predator sounds, masking intraspecific communication, or deterring an animal from crossing the rail alignment. In addition, a substantial impact would occur if the project would interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors or impede the use of native wildlife nursery sites. These impacts are evaluated here on a species-by-species basis, concluding with an evaluation of potential impacts on non-special-status terrestrial mammals.

4.1 San Joaquin Kit Fox

San Joaquin kit fox habitat is evaluated in Appendix F of the WCA. Kit fox observations in the study area have been made in the area east of the east portal of the Pacheco Pass tunnel and particularly along a least-cost north-south movement corridor that, in the project vicinity, generally follows the California Aqueduct. The kit fox likely has extremely good hearing; the related red fox can hear sounds at -15 dB at 4 kHz (Malkemper et al. 2014). The kit fox would be subject to noise effects from HSR train passage. There is a high potential that this noise would affect kit fox foraging effectiveness. There is also some potential that it would increase predation risk and, by causing the fox to avoid the rail alignment, deter the fox from crossing the alignment. However, there is considerable evidence that kit foxes will use crossings at major highways. Bremner-Harrison et al. (2007) confirmed that San Joaquin kit foxes visited crossing structures at I-5, SR 58, and SR 14 but did not pass through the structures, presumably due to low openness factors; instead they crossed the highway, and two roadkills were found. Similarly, Clevenger et al. (2010) showed that swift foxes use crossing structures on 4-lane divided highways in Colorado and South Dakota, and McCollister and van Manen (2010) showed that red and gray foxes use undercrossings on divided highways in North Carolina. Potential noise impacts on kit foxes were assessed by USFWS (2009) in its biological opinion for the Merced to Fresno Project Section of the HSR system. It determined that "noise disturbance from operation of the HST will not occur during nocturnal activities of San Joaquin kit fox in areas adjacent to the alignment from 12:00 a.m. through 6:00 a.m." and that "it is likely that San Joaquin kit fox will become quickly adapted to the increased noise disturbance generated by operation of the HST[3]." In summary, there would be a considerable potential for operational noise to affect foraging and alignment crossing by San Joaquin kit fox, and measures to minimize those effects are discussed below (Section 5.1, San Joaquin Kit Fox).

4.2 Fresno Kangaroo Rat, Badger, Dusky-Footed Woodrat, and Ringtail

Habitat for the Fresno kangaroo rat and badger is evaluated in Appendix F of the WCA. That analysis finds optimum habitat permeability for the Fresno kangaroo rat east of the Pacheco Pass tunnel (approximately from Stations B4310 to B5100). For the badger, optimum permeability exists in Coyote Valley (approximately from Stations B0665 to B1025) and throughout the Pacheco Pass area (approximately from Stations B2250 to B4310). The dusky-footed woodrat and the ringtail were not modeled, but they belong to the same "moderate mobility small fauna" movement guild as the badger; dusky-footed woodrat has been observed in Coyote Valley in camera traps documenting wildlife passage across U.S. Highway 101 (Phillips et al. 2012).

The Fresno kangaroo rat is primarily nocturnal, but its daily peak activity occurs about 20 minutes after sunset (Lockard and Owings 1974), at which time train activity would be frequent (comparable to daylight hours). There is high potential that kangaroo rats in close proximity to passing trains would display a predation avoidance response when trains pass, disrupting foraging and other behaviors at those times. Kangaroo rat passage across the alignment might be delayed until later, when train activity diminishes.

The badger, dusky-footed woodrat, and ringtail are primarily nocturnal and thus most active during the times when there is little activity on the rail alignment. Thus, these animals are at relatively low risk of predation, impaired foraging, or passage impediments due to HSR noise.

In summary, there would be a considerable potential for operational noise to affect foraging and passage by Fresno kangaroo rat. Such impacts would be unlikely for badger, dusky-footed woodrat, and ringtail.

[3] HST or "high speed train" was the term USFWS used in 2009 to refer to the HSR project.

4.3 Mountain Lion

Habitat permeability for the mountain lion is evaluated in Appendix F of the WCA. That analysis finds optimum habitat permeability in Coyote Valley (approximately from Stations B0665 to B1025) and throughout the Pacheco Pass area (approximately from Stations B2250 to B4310). Evidence from both roadkills and camera traps indicates mountain lion passage through both areas, and both areas may provide mountain lion foraging habitat. The west Pacheco Pass area is particularly important for mountain lion habitat connectivity, as it provides a nexus for movement between the Santa Cruz Mountains, Diablo Range, Gabilan Range, and inner Coast Range. The mountain lion likely has good hearing ability and uses it for prey detection, especially at night.

In Coyote Valley, train noise would be masked by Monterey Road and U.S. Highway 101 along the alignment north of Morgan Hill, but there are no important sources of masking noise to the west of this alignment. HSR noise would affect nearly the whole valley floor in that direction, extending up into the hills. There is a high potential that this noise would affect mountain lion foraging effectiveness and that it would add to other existing barriers, such as the existing rail line and U.S. Highway 101, in deterring mountain lions from crossing the valley through this area.

In the Pacheco Pass area, train noise would be substantial along upper Pacheco Creek (Stations B2350 to B3330). This area includes possibly the best mountain lion foraging habitat in the San Jose–Merced segment, i.e., the perennial reach of Pacheco Creek upstream of Casa de Fruta. There is a high potential that train noise would affect mountain lion foraging effectiveness and that it would add to the existing barriers represented by SR 152 in deterring mountain lions from crossing the valley through this area. In summary, there would be a considerable potential for operational noise to affect foraging and alignment crossing by mountain lions, and measures to minimize those effects are discussed below (Section 5.2, Mountain Lion).

4.4 Tule Elk

Tracking collar data for Tule elk in the study area (Hobbs 2017) indicate that their activity is mainly in the vicinity of San Luis Reservoir and that SR 152 constitutes a barrier to further movement northwards. However, were the elk to have access to lands in the vicinity of the rail alignment between the east portal of the Pacheco Pass tunnel and the west edge of the San Joaquin Valley (approximately from Stations B4035 to B4290), they would then be subject to the effects of train noise. Such noise could impair elk foraging and might deter them from crossing the rail alignment, which is on viaduct for several extended sections in this area. However, as the elk will not foreseeably have access to this habitat, those impacts are not expected to occur. In summary, there would not be a considerable potential for operational noise to affect Tule elk.

4.5 Townsend's Big-Eared Bat, Western Mastiff Bat, Pallid Bat, and Western Red Bat

Bats in general are vulnerable to human-caused noise. Although their ability to hunt by echolocation is well known, many bats also hunt via "passive listening," i.e., hearing their prey. Many bats use a combination of echolocation and passive listening to hunt, e.g., by using echolocation to orient themselves but passive listening to home in on prey items (Jones et al. 2016). Bat audiograms typically reveal that their hearing is most sensitive at frequencies higher than 10 kHz (Heffner et al. 2013, Figure 4), which is well above the predominant sound frequencies of HSR trains (Deng et al. 2014). Experimental exposure of bats to traffic noise, as well as to noise from other sources including synthesized white noise, has shown that bats will forage by passive listening even in a high noise environment, with foraging most limited by continuous white noise (Schaub et al. 2008). These findings suggest that HSR noise can be expected to cause some reduction in bat foraging success but that there is a low likelihood of bats avoiding areas with HSR noise. Moreover, since bats are primarily nocturnal predators, most of their foraging would occur at times when trains were infrequent and exposure brief. In summary, there would not be a considerable potential for operational noise to affect Townsend's big-eared bat, western mastiff bat, pallid bat, or western red bat.

4.6 Non-Special-Status Mammals

A wide variety of non-special-status mammalian wildlife occur in the study area, representing a wide variety of mammals—bats, insectivores, rodents, rabbits, carnivores, and ungulates (mostly deer). Apart from rabbits and insectivores, these are the same groups represented by the special-status mammals. For all these animals, an impact would be significant if it interfered substantially with the movement of any native resident or migratory wildlife species or with established native resident or migratory wildlife corridors or impede the use of native wildlife nursery sites.

Bats and burrowing animals (most rodents and rabbits, and some carnivores) are at low risk of impacts. Bats are nocturnal and primarily function at acoustic frequencies higher than those produced by HSR trains. Burrowing animals are shielded from noise by the earth, but they are at elevated risk of impacts through the mechanism of vibration (separately analyzed). Insectivores are small animals with very limited home ranges that do not undertake migrations or other seasonal movements at a scale that would conflict with the HSR alignment; moreover, most of them are also burrowing animals. Potential impacts would be greatest with larger carnivores and ungulates, which sometimes perform long-distance movements that could be impeded by the rail alignment and commonly use sound to find prey or evade predation. However, all of the common carnivores and ungulates are distinguished by their tolerance for human activity. As detailed above in Section 3, Mammalian Wildlife Responses to Noise, existing studies of mammal use of crossings in Coyote Valley and upper Pacheco Creek have all documented frequent use of crossings at U.S. Highway 101 and SR 152 by common wildlife (Phillips et al. 2012; Pathways for Wildlife et al. 2016; Pathways for Wildlife 2020). These mammals are common because they are able to forage, evade predators, breed, and move about on the landscape despite the presence of human disturbances in the form of light, noise, and activity. Their primary vulnerability to humans is related to possible loss of habitat through conversion to other cover types, an impact that is not relevant to this analysis of noise effects. In summary, there would not be a considerable potential for operational noise to affect non-special-status mammals.

5 MEASURES TO REDUCE EFFECTS

The measures described in this section could be implemented to address operational noise impacts on relevant special-status species mammals. The measures described in this section involve construction of noise barriers similar to those proposed in Final EIR/EIS Mitigation Measure BIO-MM#80 to address impacts on birds.

5.1 San Joaquin Kit Fox

Installation of noise barriers adjacent to crossing structures and in locations where San Joaquin kit fox are expected to cross under viaducts would reduce impacts by facilitating San Joaquin kit fox movements across the rail alignment and by reducing the extent and severity of impacts on kit fox foraging behavior. This measure would be most effective in the area where least-cost paths for north-south migratory movements have been identified (WCA, Appendix F1, pages F-15 to F17). The highest-value location is north of the connection of San Luis Reservoir and the O'Neill Forebay, which has been identified as a regionally critical connection for north-south movements by this species. This is the viaduct section that crosses the California Aqueduct between Stations B4245 and B4255. Secondary high-value movement corridors in the area include the viaduct sections between Stations B4156 and B4171 and between Stations B4184 and B4197, as well as the kit fox crossing structures located at Stations B4204+75, B4224+50, B4238+33, and B4262+00. Noise barriers at crossing structures would be most beneficial if located on both sides of the track and extending at least 550 feet in each direction from the crossing if the crossing is beneath a viaduct or 720 feet in each direction if the crossing is beneath an embankment. This should be sufficient to produce a large zone of reduced noise that may be attractive to the fox. Noise barriers in these locations are designed to achieve a 10 dB noise reduction at 100 feet from the track, with greater effect at lesser distances and reduced effect at greater distances, as discussed earlier (page 3.7-E-4). The barrier would reduce L_{max} levels near the rail alignment to approximately one-quarter the level that would occur in the absence of the measure. With this

measure, impacts on San Joaquin kit fox habitat use and passage across the HSR alignment would be reduced but not eliminated.

5.2 Mountain Lion

The addition of noise barriers would reduce impacts on mountain lion by facilitating movements across the rail alignment and by reducing the extent and severity of impacts on mountain lion foraging behavior. Due to the severity of existing barriers to passage through Coyote Valley, there is limited confidence that such a measure would produce observable effects. However, noise barriers could facilitate mountain lion movement across Coyote Valley and upper Pacheco Creek. Barriers would be most effective if collocated with wildlife undercrossings providing passage from across U.S. Highway 101 in Coyote Valley and across SR 152 in upper Pacheco Creek.

In Coyote Valley, noise barriers to protect wildlife crossings would be beneficial if located between Stations B0648+80 and B0754+80, depending on the alternative (Figures 2a, 2b, 2c, and 2d). In the Pacheco Creek area, the highest value site for noise barriers is between Stations B3254+70 and B3303+00 (Figure 3). This includes the highest value corridor for north-south mountain lion movement in the area and is also located directly south of two Pacheco Creek bridges and one tributary culvert on SR 152 that have all been documented by camera traps to have high use by mammalian wildlife (Pathways for Wildlife 2020). The adjacent valley of Pacheco Creek contains high-value foraging habitat for a wide variety of mammals, including mountain lions, and the barrier would reduce noise impacts on that habitat. Due to the importance of this habitat, further benefits would accrue to mountain lion habitat if the barrier were extended southwest as far as Station B3175. As discussed above for the kit fox, it would also be beneficial to place noise barriers at the crossing of the California Aqueduct at Stations B4248+00 to B4249+00 (all alternatives; Figure 4). Barriers at that location would also facilitate mountain lion movements in that area. With these measures, impacts on mountain lion habitat use and passage across the HSR alignment would be reduced but not eliminated.

APPENDIX 3.7-F: SUPPLEMENTAL ARTIFICIAL LIGHT ANALYSIS ON TERRESTRIAL WILDLIFE SPECIES

1.1 Introduction

Artificial light at night (ALAN) is here defined, for the project, as all exterior artificial light sources used during construction and operations to light the site, as well as vehicle-mounted lighting. This analysis describes the potential biological effects of that lighting, within the context of California Environmental Quality Act (CEQA) thresholds of significance and National Environmental Policy Act (NEPA) impact definitions.

This analysis applies to all terrestrial wildlife species in the study area, though it is more focused on special-status species because their existing limited populations are more vulnerable to significant impacts compared to common species having large and robust populations. Impacts on birds have been previously treated in the Wildlife Corridor Assessment (Authority 2020, Appendix C, Sections 4.5 and 6.2.3).

In this document, exposure to ALAN is assumed to occur consistent with the project as described in Chapter 2, Alternatives, of the Final Environmental Impact Report/Environmental Impact Statement (EIR/EIS), including implementation of impact avoidance and minimization features (IAMFs) and mitigation measures in the Final EIR/EIS. IAMFs and mitigation measures relevant to ALAN include the following:

- BIO-IAMF#12: “Use of facility lighting that does not attract birds or their prey to project sites. These include using non-steady burning lights (red, dual red and white strobe, strobe-like flashing lights) to meet Federal Aviation Administration requirements, using motion or heat sensors and switches to reduce the time when lights are illuminated, using appropriate shielding to reduce horizontal or skyward illumination, and avoiding the use of high-intensity lights (e.g., sodium vapor, quartz, and halogen). Lighting will not be installed under viaduct and bridge structures in riparian habitat areas.”
- BIO-MM#44: Nighttime light disturbance would be avoided near sandhill crane roost sites by not conducting any nighttime work from 1 hour before sunset to 1 hour after sunrise within 0.75 mile of observed roost sites between January 1 and March 15.
- BIO-MM#51: Nighttime light disturbance would be reduced in and adjacent to suitable habitat where known California condor roosting habitat occurs at Lover’s Leap south of State Route 152. Nighttime lighting would be focused, shielded, and directed away from the nighttime roost site. The project biologist would be on site during nighttime light use to determine the lighting risk to condors and to implement lighting avoidance measures (e.g., lighting shields) if necessary.
- BIO-MM#60: Effects on San Joaquin kit fox would be minimized; construction activities within 200 feet of any occupied dens would cease 0.5 hour after sunset and would not begin earlier than 0.5 hour before sunrise to avoid indirect impacts from artificial light on the species.
- BIO-MM#76a: “The Authority will avoid conducting ground-disturbing activities within known wildlife movement routes during nighttime hours, to the extent feasible, and will shield nighttime lighting to avoid illuminating wildlife movement corridors in circumstances where feasible.”
- BIO-MM#77a: This measure specifies, for the design of wildlife crossings, “Design entrances to minimize light reflection from train lights” and “Avoidance of artificial light at approaches to wildlife crossings.”
- BIO-MM#80: This measure requires the Authority to install 17-foot-high noise/visual barriers within a portion of the Grasslands Ecological Area (GEA) Important Bird Area (IBA), and within the Upper Pajaro River IBA, and a guideway enclosure within the main GEA IBA centered approximately at Mud Slough, to minimize effects on birds.

In this analysis, impacts of artificial light on wildlife are described as significant if either of the following CEQA significance thresholds would be exceeded:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service.
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors or impede the use of native wildlife nursery sites.

The Council on Environmental Quality NEPA regulations (40 Code of Federal Regulations [C.F.R.] Parts 1500–1508)[1] provide the basis for evaluating project impacts. As described in Section 1508.27 of these regulations, the criteria of context and intensity are considered together when determining the severity of the change introduced by the project.

- **Context—**For the analysis of impacts on biological and aquatic resources, the context would be the existing resources within the resource study area: the status of sensitive communities and species that occur or that could occur along the project corridor and the regulatory setting pertaining to biological and aquatic resources.
- **Intensity—**For the analysis of impacts on biological and aquatic resources, the intensity or severity of an impact would reflect the magnitude of the change between the existing and projected conditions—specifically, the degree to which the construction and operations of the project could affect these resources.

This analysis is organized as follows.

- Wildlife exposure to ALAN in the study area, considering both existing conditions and changes from that condition that would occur with construction of the project.
- Potential wildlife responses to ALAN, based on review of published studies of the subject.
- Impact assessment, including remarks on special-status species likely to be affected.
- Potential IAMFs to reduce the assessed impacts.

1.2 Artificial Light Exposure in the Study Area

ALAN alters natural light regimes spatially, temporally, and spectrally (Gaston et al. 2013). Spatial changes describe where ALAN occurs. Temporal changes affect both the timing and duration of ALAN exposure and include dynamic components, such as flickering and flashing. Spectral changes concern the color of the ALAN and are typically determined by the lighting source (e.g., LED, halogen, sodium vapor lamp). ALAN in biological systems can function as both a resource and as an information source (Gaston et al. 2013). As a resource, light may drive photosynthesis, or its absence may be critical to dark physiology processes. As an information source, light controls circadian clocks and photoperiodism, influences visual perception, and affects spatial orientation. The effects of ALAN on light as an information source have produced the most diverse and widely studied biological consequences.

The existing ALAN environment in the study area is depicted in Figure 1, which shows a satellite view of the study area at night (November 9, 2020, which was a cloudless night).

[1] The project is being evaluated under NEPA regulations as adopted prior to changes that occurred in 2020.

FEBRUARY 2021

Figure 1 Study Area at Night

As shown in Figure 1, the study area generally has a high level of existing light exposure from San Jose to the southern outskirts of Gilroy, though levels are appreciably lower in the Coyote Valley area. Note, however, that the alignment in Coyote Valley is colocated with an existing double track mainline used by Caltrain and by freight traffic; thus, the area has existing high exposure to operational train lighting. East of Gilroy, ALAN levels are low or very low throughout most of the alignment. Accordingly, this analysis determines potential ALAN effects to only occur in Coyote Valley and throughout the alignment east of Gilroy, where project activities have the potential to substantially alter ALAN exposure relative to existing conditions. The limits of areas (as defined in the Preliminary Engineering for Project Design Record drawings in Volume 3 of the Final EIR/EIS) with existing low ALAN exposure are shown in Table 1.

Table 1 Construction Stationing Limits of Areas with Existing Low ALAN Exposure

Area	Stationing Limits			
	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Coyote Valley	B680 to B1000	B720 to B1070	B630 to B1000	B670 to B1020
East of Gilroy	B1810 to B5335	B1810 to B5335	B1450 to B5335	B1750 to B5335

The project could cause biological effects attributable to ALAN by the following mechanisms.

- **Construction site lighting**. Site lighting is on site (i.e., within the combined temporary plus permanent impact footprint), with spillover to neighboring areas that may include wildlife habitat. Spillover would be minimized as required by BIO-MM#76a; this effect is detailed in Section 1.3.1, Continuous Lighting Effects. Light sources (spectrum) are currently dominated by metal halide light plants but would potentially be dominated by LEDs by the time the proposed work is performed. LED is a broad-spectrum source. Light intensity would vary with proximity to the light plant but would be designed to meet the Occupational Safety and Health Administration (OSHA) standard for general construction, 5 foot-candles[2] (54 lux; 29 C.F.R. § 1926.56), at the limits of the construction area. ALAN duration is potentially throughout the hours of darkness. Although directed toward the site, light sources would be visible to wildlife outside the project footprint. Night work within areas with existing low levels of ALAN and, thus, potential impacts due to construction site lighting, is only proposed in Coyote Valley and at the tunnel portals. At these locations, lighting would be minimized by implementation of BIO-MM#76a.
- **Construction vehicle lighting**. Vehicles going to and coming from the project site or vehicles operating within the project footprint may briefly direct light (headlights or spotlights) toward areas outside the project footprint. Though of short duration and limited spatial scope, lights of this intensity can influence wildlife behavior or physiology.
- **Operational site lighting**. This lighting occurs at stations and other facilities, such as the maintenance-of-way facility (MOWF) and the traction power stations. Operational site lighting would comply with BIO-IAMF#12. Operational site lighting is directed toward the site and is predominantly of a fairly low intensity. At the traction power stations, it consists of security lighting, approximately 5 lux. At the stations and MOWF, it is approximately 20 to 50 lux. Operational site lighting is continuous throughout the hours of darkness, except to the extent that it can sometimes be stopped consistent with BIO-IAMF#12. Although directed toward the site, light sources would be visible to wildlife outside the project footprint and could affect

[2] Many different units are used to measure light. This analysis primarily uses lux, which is a measure of the amount of light falling on a surface. Other common units include the lumen, which is one lux per square meter; the foot-candle, which is one lumen per square foot; and the candela, a measure of the intrinsic brightness of any point on a source of illumination. For conversion between these units, see https://www.compuphase.com/electronics/candela_lumen.htm (accessed January 19, 2021).

wildlife through the same mechanisms discussed for construction site lighting. The impact would be permanent.

- **Operational train lighting**. This lighting consists of train headlights and incidental light that may be visible at train windows. Headlights are required by Federal Railroad Administration (FRA) regulations and must have an output of 200,000 candelas. Three train headlights are required, but FRA allows a waiver that uses one headlight except at at-grade crossings; such crossings exist in Alternative 4 but not the other alternatives. The California High-Speed Rail Authority (Authority) intends to seek such a waiver, and only use three headlights near at-grade crossings; there are no such crossings within the areas specified in Table 1 (Volume 2, Appendix 2-B, Railroad Crossings, of the Final EIR/EIS). Spectrum is undefined but would likely be LED. This stimulus is bright, brief, and repetitive, occurring once at any given site for every night train passage.[3] Incidental light from train windows is of very low intensity, less than 1 lux, diminishing rapidly with distance from the train. Operational train lighting would be essentially invisible to wildlife in sections of the alignment confined by tunnels, trenches, or noise/visual barriers and would be minimized at wildlife crossings as specified by BIO-MM#77a.
- **Operations maintenance activity lighting**. This lighting includes vehicle headlights and work-site lighting of intensity comparable to construction site and construction vehicle lighting. The principal maintenance activities would be fence inspection, track inspection, and track or overhead contact system work. Fence inspection is performed during daylight hours. Track inspection inspects the entire project approximately every day. It is potentially performed at night but consists exclusively of track inspection, with all lighting directed at the track and confined within the fenceline; thus, there would be no illumination of wildlife habitat except by the headlight of the inspection train. Track or overhead contact system work also occurs entirely within the fenceline, but there could be incidental illumination of habitat in the same manner as described for construction work, and habitat could be illuminated by the headlight of the maintenance train. This lighting would affect no more than 1 mile of track per night and would be infrequent (intervals of months to years).
- **Cumulative impacts**. All forms of ALAN associated with the project are expected to make a regional contribution to light pollution and thus to skyglow, which has been associated with a variety of biological effects.

Light sources generally attenuate according to an inverse square law; with a doubling of distance from the light source, intensity decreases by a factor of four. Table 2 summarizes some common light sources relevant to this analysis and their brightness in lux.

Table 2 Illuminance Levels of Common Light Sources

Source	Brightness (lux)
Full sunlight	103,000
Cloudy day	1,000–10,000
Most homes	100–300
OSHA construction lighting requirement	54
Average street lighting	15
Average security lighting	5

[3] See Final EIR/EIS Table 2-14 for estimates of train frequency. The maximum would be 148 trains per day from 7 a.m. to 10 p.m. and 28 trains per day from 10 p.m. to 7 a.m. Over the course of the year, the night is an average of 12 hours long, with 1 hour less if civil, nautical, or astronomical twilight, respectively, are considered. There would be an average of approximately 35 evening trains and 4 morning trains each night, and these numbers vary with time of year and whether daylight savings time is observed.

Source	Brightness (lux)
Full moon	0.1–0.3
Urban skyglow	0.15
Quarter moon	0.01–0.03
Clear starry night	0.001
Cloudy night	0.00003–0.0001

Note: OSHA = Occupational Health and Safety Administration

1.3 Wildlife Responses to Artificial Light

This section discusses research related to the effects on wildlife of three forms of project-related ALAN: continuous lighting directed onto the project site that is visible to wildlife located outside the project site, intermittent lighting from vehicle or train headlights that is directed toward wildlife habitat, and lighting from all project sources that contributes to skyglow. No research appears to have assessed the effects of light from high-speed trains in other countries or locations.

1.3.1 Continuous Lighting Effects

Research into the biological effects of ALAN and its minimization has focused almost exclusively on emissions from streetlights (Gaston and Holt 2018), a form of continuous lighting directed at an animal (or plant) or its habitat. This impact would occur under the project to the extent that the air over a project site may function as foraging habitat for birds or bats and by illumination of habitat proximal to the illuminated area. Consequently, the project largely avoids the impacts that have been attributed to ALAN simply by minimizing continuous direct illumination of habitat. However, project illumination of aerial habitat would be biologically important to the extent that it is an insect attractant, and both birds and bats may approach to forage on the insects; examples include short-eared owls and bats (Rydell 1991; Canario et al. 2012). Although some bats approach and forage near such lighting, others avoid such lights (Bolliger et al 2020). Which species respond in these different ways is difficult to predict, as even bats within the same genus have sometimes been found to behave quite differently (Rotics et al. 2011).

The extent of potential illumination of habitat proximal to the illuminated area was recently investigated during night work at a high-speed rail (HSR) construction site near Corcoran, California (Bakersfield to Fresno Project Section). At this location, metal halide light plants were used to illuminate the work site. Lights were directed downward and toward the work area. The OSHA construction lighting standard of 5 foot-candles was met within approximately 130 feet from the light plant. Beyond that distance, illumination diminished rapidly, reaching a value of approximately zero relative to background at 250 feet from the light source; background was 0.04 to 0.25 lux despite the absence of a moon, indicating substantial skyglow (H.T. Harvey and Associates 2020). Based on this evidence, it is expected that effects due to unintended illumination of habitat adjacent to a work area may be encountered at distances of up to 250 feet from an operating light plant.

Apart from effects on flying animals, no research appears to have examined the effect of lighting that is not directed at organisms or their habitat, except in the case of skyglow effects, discussed in Section 1.3.3, Skyglow Effects. Since lux levels would drop to ambient within 250 feet from lights located within the project footprint, such impacts are unlikely.

1.3.2 Intermittent Lighting Effects

Vehicle headlights are the predominant mobile source of ALAN. Gaston and Holt (2018) found that “the ecological impacts that might arise from these have received almost no attention, or only passing reference, either within the literature on impacts of artificial nighttime lighting, or on the ecological impacts of roads. Where they have been considered, the focus has been on the dazzling of vertebrates and the resultant potential for these causing collisions with vehicles.”

These researchers suggested that headlights could cause biological effects through the following mechanisms (Gaston and Holt 2018).

- Headlights are focused so as to illuminate at higher intensities than commonly experienced from other sources and well above activation thresholds for many biological processes.
- Headlights are projected largely in a horizontal plane and thus can carry over long distances.
- Headlights are introduced into much more extensive areas of the landscape than experience street lighting and similar forms of ALAN.
- Headlights typically have a broad spectrum that substantially overlaps with wavelengths that influence many biological processes.
- Headlights are often expressed as a series of pulses of light (produced by passage of separate vehicles), a dynamic known to have biological impacts.

Bennie et al. (2016) found that an automotive headlight measuring 10,000 lux at 1 meter (m) produced 25 lux at 50 m and 1 lux at 100 m; this is a substantially slower drop-off than predicted by the inverse square law, a result achieved due to sophisticated reflector design in the headlight. These results suggest a value of 0.1 lux (equivalent to a full moon) at a distance of 320 m. Comparable performance in a train headlight rated at 200,000 candela (the FRA requirement[4]) would result in a brightness of 0.1 lux (equivalent to a full moon) at a distance of 1,400 m. However, train headlight drop-off as a function of angle is extreme; FRA requires only 3,000 candela at 7.5 degrees off-axis, which would diminish to full-moon brightness (0.1 lux) at a distance of 170 m. These results indicate that at any time approximately 31,066 m^2 would be illuminated by the train's headlight to a brightness greater than the full moon. Due to the extremely low curvature of the HSR track, that light is projected essentially straight down the track, and the central 21,350 m^2 would be within the fenceline. Thus, only 9,716 m^2 (2.4 acres) of habitat would be illuminated at any time and to a relatively low (but variable) intensity; moreover, this would affect habitat only within 26.5 m from the fence (similar to the area most affected by train noise). Also, note that beyond a distance of 1,007 m, the elevated light levels would only be within the fenceline and thus would not illuminate habitat. Since the area of increased illumination extends over a distance of 1,007 m and the train's speed would be 220 miles per hour (98.35 m per second) in the portions of the alignment east of the Gilroy station where baseline light levels are low or very low, the elevated illumination would last up to 10.23 seconds each time a train passed.

Headlights typically have "white" light, with a color temperature of approximately 3,500 to 4,000 degrees Kelvin; white light has a "greater likelihood of substantial emissions in key parts of the action spectra of many biological processes." Concerns have particularly been raised around emissions in the blue part of the spectrum, which may affect melatonin levels and circadian rhythms of many species (Gaston and Holt 2018).

Although the vast majority of studies of the biological impacts of ALAN have focused on continuous lighting, laboratory studies on other organisms have shown that shorter exposure to pulsed lighting can have substantial effects. Examples gleaned from a literature review by Gaston and Holt (2018) include the following.

- For the moths *Helicoverpa armigera* and *Mamestra brassicae*, 0.5-second pulses of green light decreased activity in one species, with no effect on the other.
- For the mosquito *Anopheles gambiae*, 6-, 10-, or 30-minute pulses of 150 to 870 lux produced suppression of biting activity.

[4] 49 C.F.R. Section 229.125(a)(1) requires "If a locomotive is equipped with a single-lamp headlight, the single lamp shall produce a peak intensity of at least 200,000 candela and shall produce at least 3,000 candela at an angle of 7.5 degrees and at least 400 candela at an angle of 20 degrees from the centerline of the locomotive when the light is aimed parallel to the tracks."

- For the Japanese horse-mackerel *Trachuras japonicus*, pulses of 3.0, 1.36, 0.62, and 0.15 cycles per second, at peak of 100 lux, produced general aversion to intermittent light or attraction and school confusion.
- For the rat *Rattus norvegicus*, a 1 millisecond pulse at 2,000 megawatt per square centimeter reduced pineal N-acetyltransferase and melatonin content.
- For the rat *Rattus norvegicus*, a 5- to 60-minute pulse every 2 hours at 200 to 250 foot-candles produced greater visual cell damage than continuous light exposure.
- For the rat *Rattus norvegicus*, five 1-minute pulses every 2 hours using two standard 100 watt incandescent lamps produced decreased peak nighttime serum melatonin concentrations.
- For the Syrian hamster *Mesocricetus auratus*, a 1- or 5-second pulse at 32,000 microwatts per square centimeter depressed pineal melatonin production.
- For the Djungarian hamster *Phodopus sungorus*, a 1-minute pulse at 40 to 200 lux reduced melatonin synthesis during the consecutive night.

Although these represent laboratory studies of organisms not found in the study area, they do suggest that exposure to intermittent ALAN can affect melatonin production in a variety of mammals and could have varied and potentially adverse behavioral effects in other species. Melatonin is a hormone that regulates circadian rhythms in most vertebrates. It has been linked to a wide variety of essential behaviors, such as reproduction, the sleep cycle, body temperature, and timing of seasonal changes. These results suggest a broad potential for ALAN associated with headlights to affect circadian rhythms of wildlife in adverse ways.

Besides these specific studies, pulsed lighting has been shown to elicit avoidance behavior in many animals, with limited evidence for adaptive responses (Gaston and Holt 2018); and to be less of an attractant than continuous lighting (Gehring et al. 2009). Thus, wildlife may avoid areas exposed to pulsed lighting; this would affect animal movement and habitat fragmentation (Gaston and Holt 2018).

1.3.3 Skyglow Effects

Skyglow from ALAN is primarily caused by upwardly emitted artificial light being scattered in the atmosphere by water and dust. Ground-reflected artificial light can also contribute. Skyglow can increase background nighttime sky brightness to levels of 0.2–0.5 lux, comparable with late twilight and moonlight (Gaston et al. 2017). Skyglow has the potential to disrupt both circadian clocks and photoperiodism in some species (Gaston et al. 2013). It may also mask natural light signals used for navigation, including moon position and polarized atmospheric light (Gaston et al. 2013). Skyglow alone can be sufficient to mask natural monthly and seasonal regimes of lunar sky brightness and to increase the annual number and regime of full moon equivalent hours available to organisms during the night (Davies et al. 2013). ALAN has been found to substantially alter the timing of avian reproductive biology, even at light levels comparable to a full moon (i.e., 0.3 lux; Dominoni et al. 2013).

1.4 Impact Assessment

An impact would occur if the project would have a substantial adverse effect on wildlife movement or if it were to, either directly or through habitat modifications, adversely affect any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service. Eleven special-status mammal species are potentially affected: mountain lion, San Joaquin kit fox, Tule elk, badger, ringtail, dusky-footed woodrat, Fresno kangaroo rat, Townsend's big-eared bat, western mastiff bat, pallid bat, and western red bat.

Impacts are assumed possible due to exposure to continuous or intermittent lighting. The project is assumed to not make a substantial contribution to skyglow in the study area for the following reasons, thus skyglow impacts are not assessed.

- Continuous project light sources are required, as part of project design, to minimize illumination consistent with existing requirements under law and regulation and to use lighting that does not direct light upward. Consequently, continuous light sources have a low potential to contribute to skyglow, relative to current conditions, under which upward-directed light sources are abundant throughout most of the study area.
- Intermittent project light sources are directed laterally and thus have limited potential to contribute to skyglow.

Impacts of continuous and intermittent project lighting are evaluated here on a species-by-species basis, concluding with an evaluation of potential impacts on non-special-status wildlife.

1.4.1 Mountain Lion

Mountain lion would potentially be affected in areas where the project alignment overlaps modeled lion habitat in Coyote Valley and in most of the Pacheco Pass Subsection. Within this area, effects could occur, except in those areas where the alignment is in a tunnel or where operational lighting is hidden by noise/light barrier walls. Because the project would minimize lighting of modeled habitat from continuous sources of construction lighting and operations lighting, this lighting would have little potential to affect mountain lion. Intermittent sources of both construction and operations lighting would at times be directed toward modeled habitat. Exposures would be brief but could potentially last for periods of minutes in the case of construction lighting and up to 10 seconds in the case of operational train lighting. These exposures would be minimized due to the installation of noise/light barriers at critical wildlife crossings in Coyote Valley and Pacheco Pass; thus, effects on mountain lion passage corridors would be minor. Elsewhere, areas affected at each exposure to intermittent lighting would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2, Intermittent Lighting Effects, although no literature has been found addressing intermittent light effects on mountain lion or, indeed, upon any large mammals. Nonetheless, there is a clear potential for adverse behavioral and physiological effects resulting from intermittent light exposure from both construction and operations sources.

1.4.2 San Joaquin Kit Fox

San Joaquin kit fox would potentially be affected in areas where the project alignment overlaps modeled kit fox habitat, most significantly in the Pacheco Pass Subsection east of the easternmost Pacheco Pass tunnel near the O'Neil Forebay, where individuals are more likely to occur (as they move north from occupied areas in Panoche Valley to the south). Within this area, effects could occur, except that nighttime construction would not occur in this area, and operational lighting would be hidden at locations with noise/light barrier walls; these walls are located at a critical wildlife crossing east of Pacheco Pass and would serve to minimize effects on kit fox movement corridors. Continuous sources of operations lighting would minimize lighting of modeled habitat and thus have little potential to affect kit fox. Intermittent sources of operations lighting would at times be directed toward modeled habitat. Exposures would be brief, lasting up to 10 seconds in the case of operational train lighting. Areas affected at each exposure would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2, although no literature has been found addressing intermittent light effects on kit fox or, indeed, upon any large mammals. Nonetheless, there is a clear potential for adverse behavioral and physiological effects resulting from intermittent light exposure from both construction and operations sources.

1.4.3 Tule Elk

Tule elk would potentially be affected in areas where the project alignment overlaps modeled Tule elk habitat in the Pacheco Pass Subsection. Within this area, effects could occur, except in those areas where the alignment is in a tunnel or where operational lighting is hidden by noise/light barrier walls; these walls are located at a critical wildlife crossing west of Pacheco Pass and would serve to minimize effects on Tule elk movement. Construction lighting would be limited to tunnel portals. Because the project would minimize lighting of modeled habitat from continuous sources of construction lighting and operations lighting, this lighting would have little potential to affect Tule elk. Intermittent sources of both construction and operations lighting would at times be directed toward modeled habitat. Exposures would be brief but could potentially last for periods of minutes in the case of construction lighting and up to 10 seconds in the case of operational train lighting. Areas affected at each exposure would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2, although no literature has been found addressing intermittent light effects on Tule elk or, indeed, upon any large mammals. Nonetheless, there is a clear potential for adverse behavioral and physiological effects resulting from intermittent light exposure from both construction and operations sources.

1.4.4 Badger and Ringtail

Badger and ringtail would potentially be affected in areas where the project alignment overlaps modeled badger or ringtail habitat in Coyote Valley and in most of the Pacheco Pass Subsection. Within this area, effects could occur, except in those areas where the alignment is in a tunnel or where operational lighting is hidden by noise/light barrier walls; these walls are located at critical wildlife crossings in Coyote Valley and Pacheco Pass and would serve to minimize effects on wildlife movement. In the Pacheco Pass Subsection, construction lighting would be limited to tunnel portals. Continuous sources of both construction lighting and operations lighting would minimize lighting of modeled habitat and thus have little potential to affect badger or ringtail. Intermittent sources of both construction and operations lighting would at times be directed toward modeled habitat. Exposures would be brief but could potentially last for periods of minutes in the case of construction lighting and up to 10 seconds in the case of operational train lighting. Areas affected at each exposure would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2, although no literature has been found addressing intermittent light effects on badger, ringtail, or, indeed, upon any large mammals. Nonetheless there is a clear potential for adverse behavioral and physiological effects resulting from intermittent light exposure from both construction and operations sources.

1.4.5 Dusky-Footed Woodrat and Fresno Kangaroo Rat

Dusky-footed woodrat would potentially be affected in areas where the project alignment overlaps modeled woodrat habitat in Coyote Valley and from south of Gilroy to western Pacheco Pass. Fresno kangaroo rat would potentially be affected in areas where the project alignment overlaps modeled kangaroo rat habitat in the Central Valley east of Interstate 5. Within these areas, effects could occur, except in those areas where the alignment is in a tunnel or where operational lighting is hidden by noise/light barrier walls; such a barrier is located in the Grasslands Ecological Area and would serve to minimize effects on wildlife movement. In the Pacheco Pass Subsection, construction lighting would be limited to tunnel portals, and, in the Central Valley, construction lighting would be avoided. Because the project would minimize lighting of modeled habitat from continuous sources of construction lighting and operations lighting, this lighting would have little potential to affect woodrat or kangaroo rat. Intermittent sources of both construction and operations lighting would at times be directed toward modeled habitat. Exposures would be brief but could potentially last for periods of minutes in the case of construction lighting and up to 10 seconds in the case of operational train lighting. Areas affected at each exposure would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2; adverse effects on three rodent species have been identified, although no literature has been

found addressing intermittent light effects on woodrat or kangaroo rat. Nonetheless, there is a clear potential for adverse behavioral and physiological effects resulting from intermittent light exposure from both construction and operations sources.

1.4.6 Townsend's Big-Eared Bat, Western Mastiff Bat, Pallid Bat, and Western Red Bat

These bat species are potentially present throughout the project alignment. To the extent their foraging habitat is aerial, it overlaps both the construction and operational project footprints. In areas having existing high levels of ALAN, project lighting would not substantially alter that condition, and project impacts would thus be minor, likely indistinguishable from existing conditions. Projects impacts would also be minor in tunnels. Elsewhere, the project could introduce continuous lighting to areas where it is currently absent, with a potential for effects. Continuous lighting from construction could occur only in Coyote Valley and at the tunnel portals. Continuous lighting from operations will primarily occur at traction power stations located in areas where ALAN is currently low, at stations, at tunnel portals, and at the MOWF. Lighting at tunnel portals serves as a minimization measure to discourage bat roosting in and near tunnels, which would otherwise expose them to mortality via train strike.

As discussed in Section 1.3.1, continuous project lighting is likely to be an attractant to flying insects and thus to bats. Some bats avoid lighting in spite of its effects on flying insects; however, in view of the potential food source represented by continuous project lighting, one or more of these species would likely forage near ALAN sources. The principal adverse impact of ALAN on bats is that it limits habitat access for those species that are averse to light (Azam et al. 2015). If one or more of these four species are light-averse, they would lose access to areas illuminated by continuous project lighting. Moreover, because species' foraging patterns could be affected, these species could be exposed to more indirect effects, such as increased predation risk or altered competitive relationships with less light-averse species (Azam et al. 2015). This risk can be assessed for each species.

Townsend's big-eared bat (*Corynorhinus townsendii*, sometimes called *Plecotus townsendii*). This bat is primarily a forest species and a dark-loving bat. Species of *Plecotus* have been shown to be averse to light, avoiding lighted roadways (Rydell 1992). Thus, project ALAN may represent an adverse impact on this species by reducing habitat, altering competitive relationships with less-sensitive bat species, and contributing to habitat fragmentation. Impacts associated with construction throughout the alignment would be temporary, and impacts associated with continuous lighting at project facilities and with operational maintenance lighting would be permanent.

Western mastiff bat (*Eumops perotis*). A variety of bats in the genus *Eumops* have commonly been observed foraging over and near streetlights and other ALAN sources (Rydell 2006). If the western mastiff bat shows similar behavior, project ALAN is less likely to have adverse impacts on this species.

Pallid bat (*Antrozous pallidus*). The pallid bat has an unusual foraging strategy, primarily preying upon ground-dwelling invertebrates that it captures by detecting the sounds they make (Jones et al. 2016). Thus, areas illuminated by continuous project lighting, which are almost entirely parking areas and other areas that do not provide foraging opportunities, do not constitute habitat for pallid bats, and continuous lighting does not constitute an impact on this species.

Western red bat (*Lasiurus blossevillii*). Some species in the genus *Lasiurus* have been observed foraging over and near streetlights and other ALAN sources, including the red bat *L. borealis* (Rydell 2006). If the western red bat shows similar behavior, project ALAN is less likely to have adverse impacts on this species.

All four bat species are subject to impacts of intermittent light from construction and from train operations. Intermittent sources of both construction and operations lighting would at times be directed toward bat habitat. Exposures would be brief but could potentially last for periods of minutes in the case of construction lighting and up to 10 seconds in the case of operational train

lighting. Areas affected at each exposure would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2, although no literature has been found addressing intermittent light effects on any species of bat. However, studies have found that melatonin is critical to circadian and seasonal variations in bat physiology; for example, it is involved in seasonal metabolic changes in the pallid bat reproductive cycle (Beasley et al. 1984; Beasley and Leon 1986). There is a clear potential for adverse behavioral and physiological effects resulting from intermittent light exposure from both construction and operations sources.

1.4.7 Non-Special-Status Wildlife

Non-special-status wildlife includes a wide variety of vertebrate species. These species would potentially be affected in areas where the project introduces ALAN to areas that are currently relatively dark, in Coyote Valley and from south of Gilroy to the eastern end of the alignment. Within these areas, effects could occur, except in those areas where the alignment is in a tunnel or where operational lighting is hidden by noise/light barrier walls, which are located at multiple critical wildlife crossings and would serve to minimize effects on wildlife movement. Because the project would minimize lighting of wildlife habitat from continuous sources of construction lighting and operations lighting, this lighting would have little potential to affect wildlife. Intermittent sources of both construction and operations lighting would at times be directed toward wildlife habitat. Exposures would be brief but could potentially last for periods of minutes in the case of construction lighting and up to 10 seconds in the case of operational train lighting. Areas affected at each exposure would be on the order of up to 9,716 m^2 (2.4 acres). Exposure to intermittent light has been found to potentially affect melatonin metabolism and to elicit avoidance responses, as discussed in Section 1.3.2. This would create local and temporary habitat quality reductions; however, none of the non-special-status wildlife populations are known to be vulnerable to population-level effects as a result of such impacts.

1.5 Measures to Reduce Effects

The project incorporates BIO-IAMF#12 to minimize ALAN effects on wildlife by avoiding directing continuous light sources toward wildlife habitat, avoiding use of high-intensity lights to the extent allowable (the sole exception being train headlights, which are required to be of high intensity), minimizing directing light upward or laterally, and avoiding illumination of wildlife crossings or of streams or areas of riparian habitat.

In consideration of this IAMF and other relevant mitigation measures in the Final EIR/EIS, lighting effects remain from the use of continuous lighting that may serve as an attractant to wildlife occupying nearby habitat, and the use of intermittent lighting associated with vehicles used for construction, maintenance, or operations.

There are five types of mitigation measures to address ALAN impacts (Gaston et al. 2012; Schroer and Holker 2017): (1) maintaining and creating dark areas; (2) reducing light trespass so as to direct ALAN where it is needed and to prevent it from being directed elsewhere; (3) reducing the intensity of ALAN; (4) reducing the duration of ALAN by switching off lighting sources when they are not needed; and (e) reducing biological impacts of ALAN by using illumination sources that provide sufficient human benefit while minimizing wavelengths having high biological activity. The first two of these measures have been addressed to the extent feasible, using the measures named above. The following additional measures are recommended to further reduce lighting impacts within the areas identified in Table 1.

- Minimize intensity and duration of construction lighting: Design construction lighting to be consistent with the minimum lighting levels approved by OSHA for general construction—5 foot-candles (54 lux; 29 C.F.R. § 1926.56). When performing construction in or adjoining habitat for special-status species, notify wildlife agencies of planned activities and discuss means to minimize construction effects at the proposed site. To the extent feasible, minimize duration of lighting, for example by using methods other than lighting to ensure security of the construction site during the hours it is not in use.

- Minimize intermittent construction lighting: Minimize direction of construction vehicle headlights towards offsite locations. Use low beams or turn off headlights when safety considerations permit.
- Minimize intensity and duration of operational lighting: Provide operational facility outdoor lighting consistent with minimum OSHA requirements established by 29 C.F.R. Section 1926.56. To the extent feasible, minimize duration of lighting, for example by using methods other than lighting to ensure security of facilities during hours they are not in use.
- Minimize intensity of train lighting: Provide headlights consistent with the minimum standard allowed under 49 C.F.R. Section 229.125, that is a single-lamp headlight of at least 200,000 candelas. Off-axis performance of the headlight should likewise conform to regulatory minimum standards. Obtain an FRA variance to allow use of a single headlight except near at-grade crossings.
- Minimize use of lighting at short wavelengths: A variety of studies have shown that shorter (blue) wavelengths have deleterious effects on bats. These can be eliminated, particularly if LED lighting is used and intensities are minimized (Kerbiriou et al. 2020; Lewanzik and Voight 2017). Lamps should have the lowest color temperature feasible for the desired application; green and red lighting appears to have the least wildlife impact and will be appropriate for some applications, such as security lighting (Longcore and Rich 2016). To the extent feasible, filter or specify all lamps to remove wavelengths shorter than 530 nanometers; this will avoid the wavelengths shown to cause melatonin disruption in humans and many other vertebrates (Kayumov et al. 2005).
- Implement noise/visual barriers to shield view of the operational train at essential wildlife crossings.[5]

APPENDIX 3.8-B: SUMMARY OF HYDRAULIC MODELING FOR EXISTING AND PROPOSED CONDITIONS

1 INTRODUCTION

Since publication of the Draft Environmental Impact Report/Environmental Impact Statement, the following substantive changes have been made to this appendix:

- Section 4.4.2.1, Overview of Hydraulic Model, was revised to expand the description of the one-dimensional and two-dimensional components of the Santa Clara Valley Water District's (SCVWD) Hydrologic Engineering Centers River Analysis Program (HEC-RAS) model.
- Section 4.4.2.1 and Section 4.4.2.2, Inflow Hydrograph for Hydraulic Analysis, were revised to describe the simplified SCVWD model.
- Section 4.4.2.3, Water Surface Elevations – Main Channel, was revised to state that the outputs from the hydraulic analysis for Alternative 4 showed that the proposed high-speed rail (HSR) bridge immediately upstream of the existing railroad bridge would not raise the 100-year flood profile of Guadalupe River main channel. Table 4-6 was revised to reflect these results.

1.1 Overview of the San Jose to Central Valley Wye Project Extent

The San Jose to Central Valley Wye Project Extent (project extent or project) of the San Jose to Merced Project Section (Project Section) would be a critical link in the HSR system connecting San Francisco and the San Francisco Bay Area to Los Angeles and Anaheim. The Project Section would provide HSR service between the downtown San Jose Diridon Station and a station in downtown Merced, with a Gilroy station in either downtown Gilroy or east of Gilroy. The project extent would connect San Jose to the Central Valley portion of the HSR system—the portion of the system running north to Merced and south to Fresno and Southern California—at the Central Valley Wye in Merced County.

The project extent is an approximately 90-mile portion of the 145-mile-long Project Section, which includes dedicated HSR track and systems, and station locations at Diridon, Gilroy, and Merced; a maintenance of way (MOWF) facility in the Gilroy area; and an additional maintenance of way siding (MOWS) west of Turner Springs Road in the Central Valley. The project begins as a blended system north of the San Jose Diridon Station, transitioning to a fully dedicated system from approximately Interstate (I-) 880 south to Gilroy, then east through the Pacheco Pass to Carlucci Road, the western boundary of the Central Valley Wye. For a more detailed description of the project, the five subsections in the project section, and the three end-to-end alternatives, please refer to Chapter 2, Alternatives, of this Final environmental impact report (EIR)/environmental impact statement (EIS). The design options associated with each alternative are shown in Table 1-1.

1.2 FEMA Flood Zones and Floodway

1.2.1 FEMA Flood Zones

The waterbodies with hydraulic models have floodplains and regulatory floodways delineated by the Federal Emergency Management Agency (FEMA) on Flood Insurance Rate Maps (FIRM). The floodplains in the project footprint are shown in Table 1-2. The FEMA flood hazard zones are shown in Table 1-3. FEMA flood hazard zones at specific locations in the project vicinity are discussed in more detail in Chapter 2, Overview of Hydraulic Modeling for Project Alternatives, Chapter 3, One-Dimensional Hydraulic Analysis, and Chapter 4, Combined One- and Two-Dimensional Hydraulic Modeling. Figure 1-1 through Figure 1-12 show the existing FEMA floodplains in the RSA.

Table 1-2 Floodplains in the Project Footprint

FIRM = flood insurance rate map
SCVWD = Santa Clara Valley Water District

Table 1-3 FEMA Flood Hazard Zones

Zone	Flood Hazard
High-Risk Areas	
A	Areas with a 1% annual chance of flooding and a 26% chance of flooding over the life of a 30-year mortgage. Because detailed analyses are not performed for such areas, no depths or BFEs are shown within these zones.
AE	The base floodplain where BFEs are provided. AE Zones are now used on new format FIRMs instead of A1-A30 Zones.
AH	Areas with a 1% annual chance of shallow flooding, usually in the form of a pond, with an average depth ranging from 1 to 3 feet. BFEs derived from detailed analyses are shown at selected intervals within these zones.
AO	River or stream flood-hazard areas, and areas with a 1% or greater chance of shallow flooding each year, usually in the form of sheet flow, with an average depth ranging from 1 to 3 feet. Average flood depths derived from detailed analyses are shown within these zones.
Moderate- to Low-Risk Areas	
X (shaded)	Area of moderate flood hazard, usually the area between the limits of the 100-year and 500-year floods.
X (unshaded)	Area of minimal flood hazard, usually depicted on FIRMs as above the 500-year flood level.
Coastal Areas	
V	Areas within 100-year coastal floodplains that have additional hazards associated with storm surges and waves. Approximate hydraulic analyses are performed for these areas, so BFEs are known.
VE	Areas within 100-year coastal floodplains that have additional hazards associated with storm surges and waves. Detailed hydraulic analyses are performed for these areas.
Undetermined Risk Areas	
D	Areas with possible, but undetermined flood risks. No analysis of flood hazards has been performed in these zones.

BFE = base flood elevation
FIRM = flood insurance rate map

1.2.2 FEMA Floodway

According to the Code of Federal Regulations Title 44 Section 59.1, regulatory floodway means the channel of a river or other watercourse and the adjacent land areas that must be reserved in order to discharge the base flood without cumulatively increasing the water surface elevation (WSE) more than a designated height.

In project footprint, the FEMA FIRM assigned designated floodways to Coyote Creek, Fisher Creek, and Llagas Creek. The designated floodways in the project vicinity are discussed in Chapters 2 and 3.

2 OVERVIEW OF HYDRAULIC MODELING FOR PROJECT ALTERNATIVES

In the Project Section, there are 332 waterbodies in the footprint of the project alternatives. Of the 332 waterbodies, 7 waterbodies are in Zone A floodplains, 7 waterbodies are in Zone AE floodplains, 4 waterbodies are in Zone AE floodways, 5 waterbodies are in Zone AO floodplains, and 2 waterbodies are in Zone AH floodplains. Refer to Appendix 3.8-A, Waterbodies Crossed by the Project Alternatives, for a table that lists the waterbodies in the project footprint by subsection and alternative.

Under all project alternatives, construction of new embankment sections, viaduct sections, trench sections, and tunnel sections would be in or near these existing waterbodies and their associated floodplains. Proposed maintenance facilities would be in or near existing waterbodies and floodplains under all three alternatives. In addition to the new HSR tracks and facilities, the project would also require relocation of existing roadways (Alternatives 1, 2, and 3) and relocation of existing railroad track (Alternative 2) in or near waterbodies and floodplains.

To evaluate the project's potential effects on existing floodplains, a hydraulic analysis was performed by comparing the outputs of existing- and proposed-condition hydraulic models. A total of 16 hydraulic models were provided by FEMA, SCVWD, and Pajaro River Watershed Flood Prevention Authority (PRWFPA), which covered 12 floodplains in the footprint of the project alternatives. The hydraulic model covering remaining 13 floodplains were not available. Hydraulic models provided by the Federal Emergency Management Agency are summarized in Table 2-1. Hydraulic Models provided by SCVWD and PRWFPA are summarized in Table 2-2.

Figure 2-1 through Figure 2-6 illustrate the limits of the HEC-RAS hydraulic models provided by FEMA. Figure 2-7 through Figure 2-15 illustrate the limits of the HEC-RAS hydraulic models provided by SCVWD and PRWFPA. Because the hydraulic models provided by SCVWD and FEMA are in Hydraulic Engineering Circular # 2 (HEC-2) file format because they did not include geo-referencing of the channel cross sections and the alignment of the floodplain. The alignment and limits of channel cross sections shown in these figures are taken from the alignment of channel cross sections and floodplains included in the FEMA digital FIRM. The FEMA effective hydraulic models are included in this study per request from the SCVWD to include the hydraulic analysis using the FEMA effective hydraulic models when they are available.

The existing condition hydraulic models provided by FEMA, SCVWD, and PRWFPA were in either one-dimensional or combined one-and two-dimensional hydraulic model formats. Because these two types of models require different modeling approaches, the discussion of the hydraulic analysis was sorted by the type of hydraulic analysis performed. In addition, the Soap Lake floodplain model that was developed by combining the existing available hydraulic models using different modeling approaches and assumptions is discussed in Section 5.5, Hydraulic Analysis. The discussion of the hydraulic analysis using one-dimensional hydraulic analysis are included in Chapter 3, which includes discussion of: Coyote Creek, West Little Llagas Creek, Llagas Creek (near San Martin, at East San Martin Avenue, and east of Gilroy), West Little Llagas Creek – Middle Avenue Overflow, and West Branch Llagas Creek. The discussion of the hydraulic analysis using combined one- and two- dimensional hydraulic analysis are included in Chapter 4, which includes discussion of Los Gatos Creek, Guadalupe River and Tributaries, Fisher Creek, and Uvas-Carnadero Creek. The hydraulic analysis of Soap Lake floodplain is included in Chapter 5. Table 2-1 and Table 2-2 shows report sections corresponding to the hydraulic models provided by FEMA, SCVWD, and PRWFPA.

Because the design of the HSR structures is not entirely finalized, and detailed surveys of the waterbodies in the footprint of the project alternatives are not available, all the hydraulic models used assumptions in conducting the hydraulic analysis; these assumptions are discussed in detail in Section 3.3, General Hydraulic Model Assumptions, for the one-dimensional steady-state hydraulic analysis, Section 4.2, Hydraulic Model Assumptions, for the combined one- and two-dimensional unsteady state hydraulic analysis, and in Section 5.5.5, HSR Structures and Assumptions in the Hydraulic Model, for the combined one-and two-dimensional unsteady-state

hydraulic analyses of the Soap Lake floodplain. Consequently, all the hydraulic models will have to be revised when more detailed design plans and survey data become available. The hydraulic analyses of the remaining waterbodies without existing hydraulic models that are in or near the project footprint would be performed when the channel survey information becomes available.

Figure 2-15 Location and Limits of the Available Hydraulic Models: Soap Lake (Pajaro River and Tributaries), PRWFPA Model

3 ONE-DIMENSIONAL HYDRAULIC ANALYSIS

A one-dimensional steady-state hydraulic analysis for the existing and proposed conditions were performed for the following four floodplains:

- Coyote Creek,
- West Little Llagas Creek (Mainline and Middle Avenue Overflow)
- West Branch Llagas Creek
- Llagas Creek (near San Martin, at East San Martin Avenue, at East of Gilroy, and Overbank)

This chapter provides a detailed discussion of the hydraulic analyses performed for these waterbodies for all four project alternatives.

For Coyote Creek, Llagas Creek (at San Martin, at East San Martin Avenue, at East Gilroy), the hydraulic model was provided by both FEMA and SCVWD. The hydraulic analysis was performed using both hydraulic models.

3.1 Design Tools

The HEC-RAS program, developed by the U.S. Army Corps of Engineers (USACE), was used to perform the hydraulic analyses of the four floodplains. For the hydraulic models provided in the USACE HEC-2 file format, HEC-RAS version 4.1.0 was selected to perform the hydraulic analysis.

3.2 Hydrology

The FEMA flood insurance study (FIS) for Santa Clara County, California, and Incorporated Areas, dated February 19, 2014, provided peak 100-year flow rates of the waterbodies near the project footprints. In addition, HEC-RAS hydraulic models provided by the SCVWD included 100-year flows.

The hydraulic analyses of the floodplain crossings were performed using peak 100-year flows, as specified in *Technical Memorandum 2.6.5, Hydraulics and Hydrology Design Guidelines* (Authority 2011b). Peak 100-year flows in FEMA's FIS for Santa Clara County and Incorporated Areas (last revised on February 19, 2014) (FEMA 2014) and hydraulic models provided by the SCVWD on June 3, 2016 and January 5, 2018, were compiled and reviewed (Table 3-1). The most conservative flow rates (i.e., highest) or best available data were used for the hydraulic analyses using the HEC-RAS hydraulic models. The hydraulic analysis was also performed using the FEMA effective hydraulic model and corresponding effective 100-year flood flows for the waterbodies in the FEMA detailed study. However, the FEMA effective hydraulic models may not represent the current channel condition of the floodplains, because it does not account for then recent channel improvements, new bridges, or other hydraulic structures constructed over the floodplain. Therefore, the outputs from the hydraulic analysis from the FEMA effective hydraulic models were not used to evaluate the project impacts for the waterbodies with more up-to-date hydraulic models to match the existing condition.

Table 3-1 Summary of 100-Year Flow Rates from FEMA and SCVWD

Floodplain	FEMA FIS Flow Rate (cfs)	SCVWD Flow Rate (cfs)	Type of Proposed Structures
Coyote Creek	12,630 to 15,000	15,000	New viaduct segment on the median of Monterey Road along left (west) bank of the creek and widening of Monterey Road (Alternatives 1 and 3) New embankment segment along left (west) bank of the creek and relocation of existing railroad track (Alternative 2) Share existing railroad track with UPRR and Caltrain. Second railroad track parallel to existing track would be installed at single-track segments. (Alternative 4)
West Little Llagas Creek	460 to 1,936	n/a	New viaduct segment over waterbody (Alternatives 1 and 3) New embankment segment with culvert opening over waterbody (Alternative 2) Second railroad track adjacent to existing railroad track would be installed at single-track segments (Alternative 4)
West Little Llagas Creek, Middle Avenue Overflow	658	n/a	Modifications to the roadway alignment (Alternative 2)
West Branch Llagas Creek	160 to 1,400	n/a	Modifications to the roadway alignment (Alternative 2)
Llagas Creek (at San Martin)	5,300	5,532	New viaduct segment over waterbody (Alternatives 1 and 3) New embankment segment with new bridge over waterbody, relocation of existing railroad bridge, and relocation of existing Monterey Road Bridge (Alternative 2) New 2-track railroad bridge on same alignment as existing railroad bridge (Alternative 4)
Llagas Creek (at East San Martin Avenue)	5,300	4,330	Modifications to the roadway alignment (Alternative 2)
Llagas Creek (at East Gilroy)	6,300	8,848 (17,800)[1]	New embankment segment with new bridge over creek (Alternative 3)
Llagas Overbank	900 to 7,500	n/a	New embankment segment (Alternative 3) Proposed Traction Power Switch Station (Alternatives 1 ,2 and 4)

Sources: SCVWD 2014, 2018a; FEMA 2014
FEMA = Federal Emergency Management Agency
SCVWD = Santa Clara Valley Water District
cfs = cubic feet per second
FIS = flood insurance study
UPRR = Union Pacific Railroad
[1] This flow rate of 8,848 cfs is flow remaining in the main channel of Llagas Creek at the project location. 100-year flow rate would be 17800 cfs with no spill flows on upstream of the project location.

3.3 General Hydraulic Model Assumptions

This section discusses assumptions used to perform the one-dimensional steady-state hydraulic analysis of the existing and proposed conditions. For all one-dimensional hydraulic analyses, the hydraulic model would have to be revised when more survey data and detailed project plans are available.

3.3.1 Vertical Datum (All Hydraulic Models)

Not all of the hydraulic models provided by the SCVWD provided the vertical datum referenced by the hydraulic model. Hydraulic models provided by the SCVWD without references to vertical datum were assumed to be referencing the North American Vertical Datum of 1988 (NAVD 88).

In addition, hydraulic models provided by the FEMA did not provide the vertical datum referenced by the hydraulic model. The inputs included in the FEMA hydraulic model were compared with the flood profiles included in the FEMA FIS for Santa Clara County, and it was assumed to be referencing the National Geodetic Vertical Datum of 1929 (NGVD 29) when the flood profiles from the hydraulic model are not matching with the flood profiles included in the FEMA FIS referencing NAVD 88 as vertical datum. All of the hydraulic models provided by FEMA were converted to reference NAVD 88 as vertical datum for this study.

3.3.2 Changes to Base Hydraulic Model (All Hydraulic Models)

The channel cross sections included in the HEC-2 HEC-RAS hydraulic models provided by FEMA, SCVWD, and PRWFPA were not always in the optimal locations to represent the upstream and downstream faces of the new and relocated bridges. In the proposed condition hydraulic model, the channel cross sections in the project footprint were interpolated, removed, or new cross sections were added based on available topographic information, to best represent the upstream and downstream faces of the existing and proposed bridges for all project alternatives. In this phase of the proposed project, it was assumed that these channel cross sections would best represent the channel characteristics of the waterbodies in the project footprint. These cross sections in the hydraulic models will be revised when detailed survey data becomes available.

3.3.3 Cut/Fill in the Channel Overbank Areas (All Hydraulic Models)

All four project alternatives propose modifications to the existing roadways in the project footprint. The extents of cut/fill and profile of proposed roadway were not available for all of the roadway crossings that were within the limits of the hydraulic model. Therefore, the proposed condition hydraulic model did not made changes to the channel geometry for the locations where detailed cut/fill information were not available.

3.3.4 HEC-2 Hydraulic Models

HEC-2 hydraulic model for Coyote Creek, West Little Llagas Creek, West Little Llagas Creek – Middle Avenue Overflow, West Branch Llagas Creek, Llagas Creek, and Llagas Overbank were provided to the Authority.

The hydraulic models for West Little Llagas Creek, West Little Llagas Creek - Middle Avenue Overflow, and West Branch Llagas Creek were provided to the Authority in electronical file format. These electronical files were converted into HEC-RAS version 4.1.0 to perform hydraulic analysis.

The hydraulic model for Coyote Creek, Llagas Creek, and Llagas Overbank were provided as pdf print of the inputs and outputs. The pdf print of the model inputs and outputs were compared with the hydraulic models available in the SCVWD's HEC-2/HEC-RAS library. When confirmed that they are identical, the electronic HEC-2 files from SCVWD HEC-2/HEC-RAS library are converted into HEC-RAS version 4.1.0 file format to perform hydraulic analysis.

All of the HEC-2 hydraulic models used to perform hydraulic analysis for this project were not georeferenced and did not provide alignment and limits of the channel cross sections and upstream/downstream limits of the floodplain. The upstream/downstream limits of the hydraulic

model and the extents of the channel cross sections were estimated based on following available information:

- The alignments and limits of the floodplains and channel cross sections shown in the FEMA FIRM.
- Comparison of the river stations included in the HEC-2 hydraulic model and the river stations from the flood profiles included in FEMA FIS.

The alignments and limits of channel cross sections shown in the FEMA FIRM did not provide approximate location of all of the channel cross sections included in the FEMA effective hydraulic model. In addition, the width of the channel cross sections from the FEMA FIRM did not always match with the channel widths from the corresponding channel cross sections included in the FEMA effective hydraulic model. Therefore, the location of the proposed HSR structures included in the channel geometry of the proposed condition hydraulic model were based on the best estimate from the available information.

3.3.5 Upper Llagas Flood Protection Project

SCVWD's Upper Llagas Flood Protection Project would modify the alignment of floodplains and extents of the 100-year floodplain in the project footprint. This SCVWD project is divided into two phases, and first construction phase is anticipated to occur by spring 2019 (SCVWD 2018e). The start of construction for the second construction phase is not yet determined by the SCVWD.

The SCVWD hydraulic model of Llagas Creek and tributaries showed ultimate built-out condition for this project. The hydraulic model intermediate condition after completion of Phase 1 was not available. The Authority assumed Upper Llagas Flood Protection Project would be completed before the start of construction of the San Jose to Merced segment of HSR.

The FEMA effective hydraulic models for Llagas Creek (near San Martin [Section 3.6] and at East San Martin Avenue [Section 3.7]) did not include improved channels after completion of Upper Llagas Flood Protection Project, which was assumed as existing condition for the project. Therefore, hydraulic analysis outputs from FEMA effective model were not used to evaluate project's potential floodplain impacts. The outputs from the SCVWD hydraulic model were used to evaluate the project's potential floodplain impacts.

After completion of Upper Llagas Flood Protection Project, existing floodplains for West Little Llagas Creek (Section 3.5), West Little Llagas Creek – Middle Avenue Overflow (Section 3.8), and Llagas Overbank (Section 3.11) in the project footprint would not be classified as 100-year floodplain. Therefore, hydraulic analysis outputs from FEMA effective model were not used to evaluate project's potential floodplain impacts. Because these floodplains were not included in the SCVWD hydraulic model and would be outside of the 100-year floodplain, project's potential impacts on the floodplain were not evaluated for these three existing floodplains.

3.4 Coyote Creek

3.4.1 Background Information

3.4.1.1 Floodplain Location

Coyote Creek begins at its headwaters at Anderson Reservoir and Dam and runs through the cities of Morgan Hill and San Jose before draining to the San Francisco Bay (Authority 2011a). In Morgan Hill, Coyote Creek has remained natural and includes a multipurpose recreational trail and wetlands areas.

3.4.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Numbers 60685C0407H, 60685C0426H, 60685C0428H, 60685C0429H, 60685C0437H, and 60685C0441H (FEMA 2009), the main channel of Coyote Creek in the project footprint is identified as Zone AE with floodway (Figure 3-1 and Figure 3-2).

Coyote Creek in project footprint is recognized as a floodway. Therefore, the project cannot raise the 100-year flood profile of Coyote Creek.

3.4.1.3 Project Alternatives in the FEMA Floodplain

The permanent project footprints for all four project alternatives are in the existing 100-year floodplain for Coyote Creek (Figure 3-1 and Figure 3-2). Coyote Creek flows toward the southwest in the project vicinity, and Monterey Road and existing railroad track parallels Coyote Creek in the project footprint. None of the alternatives would entail hydraulic structures spanning Coyote Creek.

The proposed HSR viaduct section (Alternatives 1 and 3) follows the southwestern bank of Coyote Creek. This alternative requires widening of Monterey Highway to construct pier columns for viaduct section in the median of Monterey Highway.

The proposed embankment section for Alternative 2 follows the southwestern bank of Coyote Creek. This alternative would require realignment of exiting Monterey Highway and railroad track to accommodate two railroad tracks for the HSR.

Alternative 4 proposes a blended at-grade track using the existing railroad track which is following the southwestern bank of Coyote Creek. This alternative require construction of additional railroad track at a single-track segment under the existing condition.

All project alternatives are proposing wildlife crossings under the existing railroad track and/or Monterey Highway.

3.4.1.4 Available Hydraulic Models

The FEMA effective hydraulic model and the SCVWD hydraulic model were available for this floodplain. Figure 3-3, Figure 3-4, and Figure 3-5 shows the approximate limits of the FEMA effective hydraulic model and the permanent project footprint for Alternatives 1 and 3, Alternative 2, and Alternative 4 along Coyote Creek, respectively. Figure 3-6, Figure 3-7, and Figure 3-8 shows the limits of the SCVWD hydraulic model and the permanent project footprint for Alternatives 1 and 3, Alternative 2, and Alternative 4 along Coyote Creek, respectively.

The FEMA effective hydraulic model provided does not include up-to-date available information that were included in the SCVWD hydraulic model. Therefore, the SCVWD hydraulic model was used to evaluate the project's potential impacts.

3.4.2 FEMA Effective Hydraulic Model

3.4.2.1 Overview of Hydraulic Model

The pier columns supporting the proposed viaduct segment on top of the Monterey Road for Alternatives 1 and 3 were represented in the proposed condition hydraulic model by adding piers into channel cross sections.

The limits of the FEMA effective model as shown in the channel information included in the FEMA digital FIRM for Santa Clara County extends into project footprint for Alternatives 2 and 4. However, the limits of the FEMA effective model where it extended into the permanent impact areas are at the locations where detailed grading plan is not available or areas with no fill inside the limits of the FEMA effective hydraulic model. Therefore, hydraulic analysis for Alternatives 2 and 4 were not performed using the FEMA effective hydraulic model.

3.4.2.2 Water Surface Elevations

The modeling results for the viaduct structure over Old Monterey Road (Alternatives 1 and 3), is shown in Table 3-2. The outputs for Alternatives 1 and 3 do not show increases in the 100-year flood profile inside the Coyote Creek main channel.

However, the flood profile of Coyote Creek from the hydraulic analysis is not representing the current condition of Coyote Creek, because it did not include the existing US 101/SR 85 Interchange Bridge over Coyote Creek located in the project vicinity. In addition, the extent of the channel cross sections in the southwestern overbank areas were not extended sufficiently to include the permanent project footprint for all proposed alternatives along Coyote Creek. Therefore, outputs from the hydraulic analysis using the FEMA effective hydraulic model was not used to evaluate the project's potential impacts on the existing 100-year floodplain.

Table 3-2 Hydraulic Modeling Results, Coyote Creek, Alternatives 1 and 3, FEMA Model

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Metcalf Rd	14,850	244.4	243.9	243.9	0.0
Upstream of Sycamore Avenue	15,000	270.5	268.5	268.5	0.0
At Coyote Creek Golf Drive	15,000	296.6	300.3	300.3	0.0
At Barnhart Ave	15,000	322.0	321.5	321.5	0.0
At US 101	15,000	355.5	348.4	348.4	0.0

Elevations are rounded to the nearest 0.1 foot.
FEMA = Federal Emergency Management Agency
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation
US = U.S. Highway

3.4.3 SCVWD Hydraulic Model

3.4.3.1 Overview of Hydraulic Model

The upstream and downstream limits of the hydraulic model were outfalls from Anderson Reservoir and at the I-280 bridge, respectively. The distance between the upstream and downstream limits of the hydraulic model is approximately 22.4 miles and is represented by 371 channel cross sections. The extents of the channel cross sections for Coyote Creek in the SCVWD model along Monterey Highway is generally wider than the current effective FEMA model.

Anderson Reservoir is in unincorporated Santa Clara County just northeast of Morgan Hill. The reservoir outfall is located approximately 2 miles east of U.S. Highway (US) 101 and approximately 3 miles east of Old Monterey Road (Alternatives 1 and 3) and existing railroad track (Alternative 2). The I-280 bridge over Coyote Creek is approximately 2 miles east of the existing San Jose Diridon Station. Coyote Creek flows parallel to the proposed HSR alignment along the Monterey Corridor Subsection.

The pier columns supporting the proposed viaduct segment on top of the Monterey Road for Alternatives 1 and 3 were represented in the proposed condition hydraulic model by adding piers into channel cross sections. The cross-sectional geometry of the western bank that is in the footprint of Alternatives 1 and 3 were modified to represent the widening of the Monterey Road. Metcalf Road bridge included in the hydraulic model was modified to represent the proposed replacement of Metcalf Road bridge (Figure 3-9).

The proposed embankment sections for Alternatives 2 and 4 were represented in the proposed condition hydraulic model by adjusting the channel geometry of the channel cross sections in the footprint of Alternative 2 (Figure 3-10) and Alternative 4 (Figure 3-11). The hydraulic model for Alternative 2 also included the relocation of Monterey Road and the new overcrossing for Palm Avenue. The pavement elevation of Monterey Road in the Alternative 2 hydraulic model was assumed to be the same as the top of rail elevation.

JANUARY 2019

Figure 3-11 Coyote Creek, HEC-RAS Channel Cross Section with Proposed Embankment Section for Alternative 4

3.4.3.2 Water Surface Elevations

The modeling results for the viaduct structure over Old Monterey Road (Alternatives 1 and 3), the embankment structure between the existing railroad tracks and Old Monterey Road (Alternative 2), and existing and the additional railroad tracks (Alternative 4) are shown in Table 3-3, Table 3-4, and Table 3-5, respectively. The outputs for Alternatives 1, 3, and 4 showed increases to the vertical profile of Coyote Creek within the limits of the hydraulic model. The outputs for Alternative 2 showed a WSE increase of approximately 0.05 foot at the Palm Avenue overcrossing.

3.5 West Little Llagas Creek

3.5.1 Background Information

3.5.1.1 Floodplain Location

West Little Llagas Creek is a tributary of Llagas Creek that flows through the City of Morgan Hill and San Martin (census-designated place). The confluence with Llagas Creek is immediately downstream of the US 101 cross culvert in San Martin, at 37° 6'21.22" North, 121°36'44.54"West. The existing railroad bridge over West Little Llagas Creek is located approximately 3,700 feet west of the US 101 cross culvert.

West Little Llagas Creek is in the footprint of Upper Llagas Flood Protection Project, and is potentially subject to the USACE Section 404 and 408 permitting process.

3.5.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Numbers 60685C0607H and 60685C0626H (FEMA 2009, 2014), the main channel and overbank flow of West Little Llagas Creek in the project footprint for all four Alternatives is identified as Zone AE (Figure 3-12).

West Little Llagas Creek in the project footprint is recognized as FEMA 100-year floodplain. Therefore, project cannot raise the flood profile of West Little Llagas Creek by more than 1.0 foot.

SCVWD's Upper Llagas Flood Protection Project would reroute West Little Llagas Creek to flow southeast, west of Monterey Highway (see Reach 7a in Figure 3-13). With completion of Upper Llagas Flood Protection Project, rerouted West Little Llagas and the 100-year floodplain for West Little Llagas Creek would be located outside of the project footprint for all four alternatives (Figure 3-14). Therefore, project's potential floodplain impacts were not evaluated for the existing West Little Llagas Creek in the project footprint.

3.5.1.3 Project Alternatives in the FEMA Floodplain

The project footprints for all four project alternatives are in the existing 100-year floodplain for West Little Llagas Creek (Figure 3-12).

Alternatives 1 and 3 propose viaduct segment over the existing 100-year floodplain for West Little Llagas Creek at approximately station 1237+00 and approximately 1,800 feet west of the existing railroad crossing over the creek. The width of the Zone AE floodplain measured along the centerline of the proposed track alignment for Alternatives 1 and 3 is approximately 1,900 feet, and the proposed pier columns would be located inside the existing 100-year floodplain.

Alternative 2 proposes new embankment section adjacent to the east side of the existing railroad track. This alternative would remove existing railroad bridge over West Little Llagas Creek and replace it with the new cross culvert for below existing railroad track and proposed HSR embankment at approximately station 1307+50. The width of the Zone AE floodplain measured along the centerline of the proposed track alignment for Alternative 2 is approximately 2,700 feet.

Alternative 4 proposes a blended at-grade segment using the existing railroad track, where existing single-track segment would be modified to double-track segment. This alternative would remove existing railroad bridge and replace it with new cross culvert at same location as the existing bridge, located at approximately station 1257+00. The width of the Zone AE floodplain measured along the centerline of the proposed track alignment for Alternative 4 is approximately 2,700 feet.

3.5.1.4 Available Hydraulic Models

The FEMA effective hydraulic model and SCVWD hydraulic model were available for West Little Llagas Creek.

Because the SCVWD hydraulic model only included the post-project condition for the Upper Llagas Creek Flood Protection Project, West Little Llagas Creek included in the hydraulic model was located outside of the project footprint. Therefore, SCVWD hydraulic model was not used to evaluate potential floodplain impacts from the project.

The hydraulic analysis was performed using FEMA's effective hydraulic model. Figure 3-15, Figure 3-16, and Figure 3-17 shows the approximate limits of the FEMA effective hydraulic model and the permanent project footprint for Alternatives 1 and 3, Alternative 2, and Alternative 4 at West Little Llagas Creek, respectively. However, because existing condition for HSR was assumed to be after completion of Upper Llagas Flood Protection Project, the outputs from the hydraulic analysis would not be used to evaluate the project's potential impact on the existing floodplain.

3.5.2 FEMA Effective Hydraulic Model

3.5.2.1 Overview of Hydraulic Model

The upstream and downstream limits of West Little Llagas Creek in the FEMA effective hydraulic model were approximately 1,800 feet upstream of Llagas Road Bridge (approximately 22,590 feet upstream of the existing railroad bridge) and the outfall to Llagas Creek (approximately 4,420 feet downstream of the existing railroad crossing).

The pier columns supporting the viaduct segment over West Little Llagas Creek under Alternatives 1 and 3 were included in the proposed condition hydraulic model simulating the new proposed viaduct segment over the existing floodplain. The span length of the pier columns used in the hydraulic model was approximately 110 feet (Figure 3-18).

The embankment section immediately downstream (east) of the existing railroad track under Alternative 2 was represented in the hydraulic model by widening the footprint of the existing railroad bridge (Figure 3-19). The size of the bridge opening was set to be a 48-foot by 5-foot box culvert to match the proposed project plans for this alternative.

Alternative 4 would use the existing two-track segment near the existing West Little Llagas Creek bridge. There would be no changes to the vertical profile of railroad track near the existing West Little Llagas Creek bridge. The existing bridge structure would be replaced by a proposed 48-foot by 5-foot box culvert (width × height, Figure 3-20) in this alternative.

JANUARY 2019

Figure 3-20 West Little Llagas Creek, HEC-RAS Channel Cross Section with Proposed Embankment Section for Alternative 4

3.5.2.2 Water Surface Elevations

The modeling results for Alternatives 1 and 3 are shown in Table 3-6. The proposed pier columns crossing the West Little Llagas Creek floodplain would not increase the 100-year flood profile of West Little Llagas Creek. The proposed railroad track is approximately 50 feet above the 100-year WSE of West Little Llagas Creek.

The modeling results for Alternative 2 are shown in Table 3-7. The proposed embankment section and new cross culvert proposed for Alternative 2 did not show increases in the 100-year flood profile of West Little Llagas Creek. The elevation difference between top of rail (approximately 323 feet NAVD) and 100-year WSE is approximately 6 feet.

The modeling results for Alternative 4 are shown in Table 3-8. The proposed embankment section and new cross culvert proposed for Alternative 4 did not show increases to the 100-year flood profile of West Little Llagas Creek. The elevation difference between top of rail (approximately 319.1 feet NAVD) and the 100-year WSE is approximately 2.1 feet. This elevation difference would not meet the HSR's design freeboard criteria for during the 100-year storm event.

Table 3-6 Hydraulic Modeling Results, West Little Llagas Creek, Alternatives 1 and 3

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Llagas Avenue	3,246	308.5	313.0	313.0	0.0
At proposed viaduct segment	3,280	309.0	313.1	313.1	0.0

3.6 Llagas Creek (near San Martin)

3.6.1 Background Information

3.6.1.1 Floodplain Location

Llagas Creek flows through the cities of San Martin, Morgan Hill, and Gilroy. West Little Llagas Creek, Madrone Channel, and East Little Llagas Creek meet to form Upper Llagas Creek (Authority 2011a). Buena Vista Avenue divides Upper and Lower Llagas Creek. Lower Llagas Creek meets West Branch Llagas Creek at SR 152 before it drains to the Pajaro River.

Llagas Creek near San Martin is subject to the USACE Section 404 and 408 permitting process.

3.6.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Number 60685C0626H (FEMA 2009), the main channel and overbank flow of Llagas Creek near the Monterey Highway bridge and railroad bridge is identified as Zone AE and floodway (Figure 3-21). The width of the floodway varies from approximately 80 feet to 130 feet in the footprint of the project alternatives. On the north side of the main channel, the overbank flood flow from West Little Llagas Creek are designated as Zone AE and AO floodplains.

SCVWD's Upper Llagas Flood Protection project modify Llagas Creek at the Monterey Highway crossing and would modify the footprint of the Zone AE and floodway, but the limits of the 100-year floodplain would still remain in the project footprint for all four project alternatives (Figure 3-22).

Llagas Creek near San Martin in project footprint is recognized as a floodway. Therefore, the project cannot raise the 100-year flood profile of Llagas Creek.

3.6.1.3 Project Alternatives in the FEMA Floodplain

Alternatives 1 and 3 propose a viaduct segment, which would cross the main channel of Llagas Creek at approximately station 1280+00. The location of the crossing is approximately 140 feet downstream (east) of the existing railroad crossing over Llagas Creek. The width of the floodplain and floodway measured along the proposed track alignment of these alternatives is approximately 525 feet. After completion of the Upper Llagas Flood Protection Project, the width of the floodplain and floodway measures along the proposed track alignment would be reduced to approximately 210 feet.

The proposed embankment section with the railroad bridge over Llagas Creek under Alternative 2 would cross Llagas Creek at approximately station 1352+00. The location of the creek crossing is approximately 100 feet upstream (west) of the existing railroad crossing over Llagas Creek. The

width of the floodplain and floodway measured along the proposed track alignment of this alternative is approximately 1,600 feet. After completion of the Upper Llagas Flood Protection Project, the width the floodplain and floodplain measure along relocated Monterey Highway, relocated Union Pacific Railroad (UPRR) track, and proposed HSR track, would be approximately 420 feet, 130 feet, and 110 feet.

Alternative 2 would also entail the relocation of the Monterey Road bridge and existing railroad bridge over Llagas Creek. The existing roadway and railroad bridges would be removed under this alternative. In addition, this Alternative would require modifications to the Llagas Creek channel that would be modified as part of the first phase of the Upper Llagas Flood Protection Project.

The proposed blended at-grade track with a railroad bridge over Llagas Creek for Alternative 4 would cross Llagas Creek at approximately station 1352+00. The existing single-track bridge over Llagas Creek would be replaced by a two-track bridge in the same alignment, extending to the west (upstream). There would be no changes to the vertical profile of railroad track on the bridge approach areas, and there would be no changes to Monterey Highway west (upstream) of the existing railroad bridge. The width of the existing FEMA floodplain and floodway measured along the existing railroad is approximately 500 feet. After completion of the Upper Llagas Flood Protection Project, the width of the floodplain and floodway measured along the proposed HSR track (shared with Caltrain and UPRR) would be approximately 130 feet.

3.6.1.4 Available Hydraulic Models

The FEMA effective hydraulic model and the SCVWD hydraulic model were available for this waterbody. Figure 3-23, Figure 3-24, and Figure 3-25 shows the approximate limits of the FEMA effective hydraulic model at Llagas Creek near San Martin with the project footprint for Alternatives 1 and 3, Alternative 2, and Alternative 4, respectively. Figure 3-26, Figure 3-27, and Figure 3-28 shows the limits of the SCVWD hydraulic model at Llagas Creek near San Martin with the project footprint for Alternatives 1 and 3, Alternative 2, and Alternative 4, respectively.

The FEMA effective hydraulic model provided does not include up-to-date available information that were included in the SCVWD hydraulic model. Therefore, SCVWD hydraulic model was used to evaluate the project's potential impacts.

The FEMA effective hydraulic models for Llagas Creek (near San Martin) did not include improved channels after completion of Upper Llagas Flood Protection Project, which was assumed as existing condition for the project. Therefore, hydraulic analysis outputs from FEMA effective model were not used to evaluate project's potential floodplain impacts. The outputs from the SCVWD hydraulic model were used to evaluate the project's potential floodplain impacts.

3.6.2 FEMA Effective Hydraulic Model

3.6.2.1 Overview of Hydraulic Model

The upstream and downstream limits of the FEMA effective hydraulic model for Llagas Creek near San Martin were approximately 3,900 feet upstream of the existing railroad bridge and approximately 780 feet downstream of the existing railroad bridge.

The pier columns supporting the viaduct segment under Alternatives 1 and 3 were represented in the proposed condition hydraulic model for Alternatives 1 and 3 using the bridge function in HEC-RAS.

The relocated Monterey Road bridge, relocated existing railroad bridge, and proposed HSR bridge over Llagas Creek under Alternative 2 were represented in the proposed condition hydraulic model by adding interpolated channel cross sections and removing existing channel cross sections that were in conflict with the proposed bridge footprint.

The proposed condition hydraulic model for Alternative 4 replaced an existing single-track railroad bridge included in the base hydraulic model with the proposed two-track railroad bridge.

3.6.2.2 Water Surface Elevations

The modeling results for Alternatives 1 and 3 are shown in Table 3-9. The proposed pier columns crossing the Llagas Creek floodplain would increase the floodplain and floodway elevation by approximately 0.4 foot or less. (Table 3-9).

The modeling results for Alternative 2 are shown in Table 3-10. The relocation of the existing Monterey Road and railroad bridge and construction of a new bridge over Llagas Creek with a channel geometry not including improvements from the Upper Llagas Flood Protection Project would increase the 100-year flood profile of Llagas Creek upstream of the relocated Monterey Highway Bridge.

The modeling results for Alternative 4 are shown in Table 3-11. The proposed removal and replacement of existing single-track bridge with a proposed double-track bridge would raise the 100-year flood profile of Llagas Creek on upstream of the proposed railroad bridge.

The current effective FEMA hydraulic model assumed a smooth channel with minimal vegetation growth, but the existing channel shows moderate to dense vegetation growth in the main channel upstream and downstream of Monterey Road Bridge and the existing railroad bridge. In addition, Phase 1 of the Upper Llagas Flood Protection Project, expected to start construction in the Year 2019, would modify the creek channel upstream of the existing Monterey Bridge. Because the current effective FEMA hydraulic model does not represent these two existing project conditions, the hydraulic analysis of the existing and proposed conditions were also performed using the hydraulic model of Llagas Creek and tributaries provided by SCVWD as comparison, and is discussed in Section 3.6.3, SCVWD Hydraulic Model.

UPRR = Union Pacific Railroad

3.6.3 SCVWD Hydraulic Model

3.6.3.1 Overview of Hydraulic Model

The upstream and downstream limits of Llagas Creek in the SCVWD hydraulic model were at Atherton Way Hidden Pond (approximately 3,440 feet upstream of the existing railroad bridge) and immediately upstream of State Route 152 (approximately 51,200 feet downstream of the existing railroad bridge), respectively (Figure 2-12).

The channel cross sections included in the base hydraulic model at the project location were not located to best represent the potential changes from the proposed project. Therefore, channel cross sections in the SCVWD hydraulic model upstream and downstream of the existing Monterey Highway Bridge and existing railroad bridge were replaced with the channel cross sections based on the proposed grading plan for the Upper Llagas Flood Protection Project provided by SCVWD on December 2017 (SCVWD 2017).

The setup of the viaduct segment crossing Llagas Creek for Alternatives 1 and 3 in the SCVWD hydraulic model is same as the setup for the proposed condition for FEMA effective hydraulic model.

The relocated railroad bridge and the proposed HSR bridge over Llagas Creek under Alternative 2 were added in between the new channel cross sections in the hydraulic model. The channel geometry was adjusted at the locations where Alternative 2 proposed changes to the channel geometry of Llagas Creek after completion of the Upper Llagas Flood Protection Project.

The proposed condition hydraulic model for the Alternative 4 replaced existing single-track railroad bridge included in the base hydraulic model with a proposed two-track railroad bridge.

3.6.3.2 Water Surface Elevations

The modeling results for Alternatives 1 and 3 are shown in **Table 3-12**. In the proposed conditions, the pier columns crossing the Llagas Creek floodplain would not increase the vertical profile and horizontal extents of the existing Llagas Creek 100-year floodplain at Monterey Highway. The outputs from hydraulic model shows the 100-year flow would be mostly contained in the main channel of Llagas Creek and the proposed pier columns would have minimal contact with the 100-year flow.

The modeling results for Alternative 2 are shown in Table 3-13. The relocation of the existing Monterey Road and railroad bridge and construction of a new bridge over Llagas Creek would not increase the vertical profile and horizontal extents of the existing Llagas Creek 100-year floodplain at Monterey Highway.

The modeling results for Alternative 4 are shown in Table 3-14. The proposed removal and replacement of the existing single-track bridge with a proposed double-track bridge would not increase the 100-year flood profile of Llagas Creek on the upstream side of the proposed railroad bridge.

Table 3-12 Hydraulic Modeling Results, Llagas Creek (near San Martin), Alternatives 1 and 3

3.7 Llagas Creek (at East San Martin Avenue)

3.7.1 Background Information

3.7.1.1 Floodplain Location

Llagas Creek flows through the cities of San Martin, Morgan Hill, and Gilroy. West Little Llagas Creek, Madrone Channel, and East Little Llagas Creek meet to form Upper Llagas Creek (Authority 2011a). Buena Vista Avenue divides Upper and Lower Llagas Creek. Lower Llagas Creek meets West Branch Llagas Creek at SR 152 before it drains to the Pajaro River.

Llagas Creek at East San Martin Avenue would be subject to the USACE Section 404 and 408 permitting process.

3.7.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Number 60685C0628H (FEMA 2009), the main channel and overbank flow of Llagas Creek near the existing East San Martin Avenue bridge is identified as Zone AE and floodway (Figure 3-29). This figure also shows Zone AE on east side of the mainline Llagas Creek, which would be discussed in detail in Section 3.8, West Little Llagas Creek, Middle Avenue Outflow.

SCVWD's Upper Llagas Flood Protection Project would modify Llagas Creek at East San Martin Avenue and would modify the footprint of the Zone AE and floodway (Figure 3-30).

Llagas Creek near San Martin in the project footprint is currently recognized as a floodway. Therefore, the project cannot raise the 100-year flood profile of Llagas Creek.

3.7.1.3 Project Alternatives in the FEMA Floodplain

The project footprint for Alternative 2 is in the existing 100-year floodplain for Llagas Creek at East San Martin Avenue, before and after completion of Upper Llagas Flood Protection Project (Figure 3-29 and Figure 3-30).

The project footprints for the remaining three alternatives are located outside of the limits of Llagas Creek floodplain/floodway at East San Martin Avenue, both before and after the completion of the Upper Llagas Flood Protection Project.

Alternative 2 proposes to change the alignment of East San Martin Avenue, which includes removal of the existing East San Martin Avenue bridge over Llagas Creek and construction of a new roadway bridge located approximately 300 feet upstream (north) of the existing bridge.

3.7.1.4 Available Hydraulic Models

The FEMA effective hydraulic model and the SCVWD hydraulic model were available for this waterbody. Figure 3-31 shows the approximate limits of the FEMA effective hydraulic model with the project footprint for Alternative 2. Figure 3-32 shows the limits of the SCVWD hydraulic model with the project footprint for Alternative 2.

The FEMA effective hydraulic models for Llagas Creek (at East San Martin Avenue) did not include improved channels after completion of Upper Llagas Flood Protection Project, which was assumed as an existing condition for the project. Therefore, hydraulic analysis outputs from FEMA effective model were not used to evaluate project's potential floodplain impacts. The outputs from the SCVWD hydraulic model were used to evaluate the project's potential floodplain impacts.

Figure 3-32 Llagas Creek (At East San Martin Avenue), Plan View of SCVVWD Hydraulic Model with Project Footprint for Alternative 2

3.7.2 FEMA Effective Hydraulic Model

3.7.2.1 Overview of Hydraulic Model

The upstream and downstream limits of FEMA effective hydraulic model for Llagas Creek at East San Martin Avenue were approximately 5,300 feet upstream of the existing East San Martin Road Bridge and approximately 21,920 feet downstream of the existing East San Martin Road Bridge.

For the proposed condition hydraulic model for Alternative 2, the existing East San Martin Road Bridge was removed and the new bridge was placed approximately 300ft upstream.

The proposed condition hydraulic model for Alternative 2 removed the existing East San Martin Road Bridge included in the base hydraulic model and added proposed East San Martin Road Bridge approximately 300 feet upstream (north).

The FEMA effective hydraulic model provided two flooding scenarios for the 100-year storm event. The first scenario allowed overbank flows to flow outside of the main channel of Llagas Creek within the model limits. The second scenario used the “Encroachment” function in HEC-RAS to force the flows to remain inside a narrower assigned area of Llagas Creek channel within the model limits. The hydraulic analysis of existing and proposed conditions were performed for both flooding scenarios.

The Manning’s roughness coefficient assigned in the FEMA effective hydraulic model is 0.025 and 0.030, which represents smooth, well maintained channel with minimal vegetation growth and minimal obstructions to the flood flow. This input in the FEMA effective hydraulic model may not represent the existing site condition at the beginning of construction for project. The existing site condition shows moderate to dense vegetation growth in the main channel and embankment slopes of Llagas Creek near East San Martin Avenue Bridge, which would be represented using higher Manning’s roughness coefficient value.

3.7.2.2 Water Surface Elevations

The modeling results for the Alternative 2 near the proposed East San Martin Road Bridge are shown in Table 3-15 and Table 3-16 for without and with overbank flows. The outputs for Alternative 2 with overbank flows showed decreases in 100-year flood profile immediately upstream of the relocated East San Martin Road Bridge over Llagas Creek. However, the 100-year flood profile with no overbank flood flows showed increases in 100-year flood profile immediately upstream of the relocated East San Martin Road Bridge over Llagas Creek. The change in 100-year flood profile attenuated at the next upstream bridge crossing (Llagas Avenue) for both cases.

Table 3-15 Hydraulic Modeling Results, Llagas Creek (at East San Martin Avenue), Alternative 2, with Overbank Flow

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Church Avenue	4,330	264.1	259.2	259.2	0.0
At relocated East San Martin Avenue Bridge	4,330	288.3	288.4	286.6	(1.8)
At Llagas Avenue	4,330	300.8	298.8	298.8	0.0

Elevations are rounded to the nearest 0.1 foot.
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

Table 3-16 Hydraulic Modeling Results, Llagas Creek (at East San Martin Avenue), Alternative 2, with No Overbank Flow

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Church Avenue	4,330	264.1	263.2	263.2	0.0
At relocated East San Martin Avenue Bridge	4,330	288.3	288.7	291.2	2.5
At Llagas Avenue	4,330	300.8	300.7	300.7	0.0

(Parentheses) indicate negative values
Elevations are rounded to the nearest 0.1 foot.
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

When using the FEMA effective hydraulic model to determine the changes in the 100-year flood profile of Llagas Creek for Alternative 2, the potential floodplain impacts were controlled by the use of “Encroachment” function in HEC-RAS hydraulic model. In addition, the FEMA effective hydraulic models for Llagas Creek (near San Martin) would not represent the existing condition for the project.

Therefore, FEMA effective hydraulic model for Llagas Creek at East San Martin Avenue would not be suitable to evaluate the project’s potential impacts on the existing 100-year floodplain. The hydraulic analysis was also performed using the SCVWD’s hydraulic model as a comparison.

3.7.3 SCVWD Model

3.7.3.1 Overview of Hydraulic Model

The SCVWD hydraulic model for Llagas Creek at East San Martin Avenue is same as the hydraulic model described in Section 3.6, Llagas Creek (near San Martin). The setup of the proposed condition hydraulic model for Alternative 2 is same as the FEMA effective hydraulic model described in Section 3.7.2, FEMA Effective Hydraulic Model.

3.7.3.2 Water Surface Elevations

The modeling results for the Alternative 2 near the proposed East San Martin Road Bridge are shown in Table 3-17. The outputs for Alternative 2 did not show increases in 100-year flood profile near the relocated East San Martin Road Bridge over Llagas Creek.

Table 3-17 Hydraulic Modeling Results, Llagas Creek at East San Martin Avenue, Alternative 2

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Church Avenue	4,330	264.0	263.3	263.3	0.0
At relocated East San Martin Avenue Bridge	4,330	286.0	287.1	287.0	(0.1)
At Llagas Avenue	4,330	300.0	298.7	298.7	0.0

(Parentheses) indicate negative values
Elevations are rounded to the nearest 0.1 foot.
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

3.8 West Little Llagas Creek, Middle Avenue Overflow

3.8.1 Background Information

3.8.1.1 Floodplain Location

West Little Llagas Creek is a tributary of Llagas Creek that flows through the City of Morgan Hill and San Martin (census-designated place). The confluence with Llagas Creek is immediately downstream of US 101 cross culvert in San Martin, at 37° 6'21.22" North, 121°36'44.54"West. Existing railroad bridge over West Little Llagas Creek is located approximately 3,700 feet west of the US 101 cross culvert.

3.8.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Numbers 60685C0626H and 60685C0626H (FEMA 2009, 2014), the main channel of West Little Llagas Creek downstream (east) of the existing railroad crossing does not have capacity to convey the 100-year flow, and the overbank flow on south side sheet flows south and does not re-enter the main channel of West Little Llagas Creek (Figure 3-33). The overbank flow outfalls into Llagas Creek near East San Martin Avenue Bridge.

West Little Llagas Creek in the project footprint is recognized as a FEMA 100-year floodplain. Therefore, project cannot raise the flood profile of West Little Llagas Creek by more than 1.0 foot.

SCVWD's Upper Llagas Flood Protection Project would reroute West Little Llagas Creek to flow southeast, west of Monterey Highway (see Reach 7a in Figure 3-13).

With completion of Upper Llagas Flood Protection Project, the rerouted West Little Llagas would outfall into Llagas Creek on west of Monterey Highway and would no longer travel at the locations where the existing FIRM shows overbank flood flow flowing south along the west side of US 101. West Little Llagas Creek – Middle Avenue Overflow would no longer be classified as 100-year floodplain after completion of the Upper Llagas Flood Protection Project (Figure 3-34).

3.8.1.3 Project Alternatives in the FEMA Floodplain

The project footprint for Alternative 2 is in the existing 100-year floodplain for West Little Llagas - Middle Avenue Overflow. The project footprints for the other three alternatives are located outside of the limits of the existing 100-year floodplain.

Alternative 2 proposes to change the alignment of East San Martin Avenue, which includes removal of the existing East San Martin Avenue bridge over Llagas Creek and construction of a new roadway bridge located approximately 300 feet upstream (north) of the existing bridge. The proposed eastern bridge approach would introduce fill inside the existing floodplain. This bridge

approach area would not be classified as a fill inside the existing floodplain after completion of the Upper Llagas Flood Protection Project.

The project footprints for the remaining three alternatives are located outside of the limits of the 100-year floodplain for West Little Llagas - Middle Avenue Overflow, both before and after the completion of the Upper Llagas Flood Protection Project.

3.8.1.4 Available Hydraulic Models

FEMA effective hydraulic model was available to perform the hydraulic analysis of this waterbody and was used to perform the hydraulic analysis. Figure 3-35 shows the approximate limits of the FEMA effective hydraulic model and the permanent project footprint for Alternative 2 at West Little Llagas Creek Middle Avenue Overflow.

Upper Llagas Flood Protection Project would remove existing 100-year floodplain assigned to West Little Llagas Creek – Middle Avenue Overflow. Therefore, the SCVWD hydraulic model of Llagas Creek and tributaries for the Upper Llagas Flood Protection Project did not include West Little Llagas Creek – Middle Avenue Overflow. Hydraulic analysis of West Little Llagas Creek – Middle Avenue Overflow was not performed using the SCVWD hydraulic model.

As stated in Section 3.3.5, Upper Llagas Flood Protection Project, West Little Llagas Creek – Middle Avenue Overflow would not be recognized as a 100-year floodplain with completion of the Upper Llagas Flood Protection Project. The outputs from the hydraulic analysis were not used to evaluate the project's potential impact on the existing floodplain.

Note: this figure does not display channel cross sections included in the hydraulic model.

Figure 3-35 West Little Llagas Creek Middle Avenue Overflow, Plan View of FEMA Effective Hydraulic Model with Project Footprint for Alternative 2

3.8.2 FEMA Effective Hydraulic Model

3.8.2.1 Overview of Hydraulic Model

The FEMA FIRM and FIS for Santa Clara County did not provide location of the channel cross sections relative to the project footprint for Alternative 2. The channel cross sections included in the hydraulic model was replaced with channel cross sections with known locations to allow the comparison of the existing and propose conditions.

The proposed East San Martin Avenue Bridge over Llagas Creek and the bridge approach for Alternative 2 would be elevated from the existing grade to provide sufficient freeboard for the proposed bridge over Llagas Creek. The fill for the eastern bridge approach area that are within the limits of the FEMA effective hydraulic model were represented by adjusting the channel cross section.

3.8.2.2 Water Surface Elevation

The modeling results for West Little Llagas Creek – Middle Avenue Overflow for Alternative 2 near the proposed East San Martin Road Bridge are shown in Table 3-18. The outputs for Alternative 2 showed increases in 100-year flood profile immediately on upstream (east) of the areas obstructed by the proposed bridge approach area.

As stated in Sections 3.3.5 and 3.8.1, Background Information, the FEMA effective hydraulic model for West Little Llagas Creek – Middle Avenue Overflow would not represent the existing project conditions for the HSR. Because West Little Llagas Creek – Middle Avenue Overflow would not be classified as 100-year floodplain, mitigation measures would not be required.

Table 3-18 Hydraulic Modeling Results, West Little Llagas Creek, Alternative 2

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Outfall to Llagas Creek at East San Martin Avenue	658	n/a	286.0	286.0	0.0
500 feet upstream (east) of outfall	658	n/a	287.1	287.6	0.5
900 feet upstream (east) of outfall	658	n/a	289.5	289.6	0.1

Elevations are rounded to the nearest 0.1 foot.
This model represents overbank flood flow with undefined channel. There is no channel bank represented in the hydraulic model.
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

3.9 West Branch Llagas Creek

3.9.1 Background Information

3.9.1.1 Floodplain Location

The West Branch Llagas Creek is tributary of Llagas Creek, flowing through the cities of San Martin and Gilroy on west side of Monterey Highway and existing railroad track.

3.9.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Numbers 06085C0628H, 06085C0636H, and 06085C0637H (FEMA 2009), the main channel and overbank flow of West Branch Llagas Creek flowing parallel on the west side of Monterey Highway is identified as Zone AE and floodway (Figure 3-36).

3.9.1.3 Project Alternatives in the FEMA Floodplain

The permanent project footprint for Alternative 2 is in the existing 100-year floodplain for West Branch Llagas Creek (Figure 3-36). The permanent impact areas for the remaining three project alternatives are outside of the limits of the existing FEMA 100-year floodplain of West Branch Llagas Creek.

There are no existing/proposed railroad bridge over West Branch Llagas Creek. Alternative 2 proposes grade separation of the existing roadways crossing the existing railroad and realignment of Monterey Highway traveling parallel to the existing railroad track on the west side. In the footprint of the existing 100-year floodplain/floodway of West Branch Llagas Creek, Alternative 2 proposes ground excavation for the roadway grade separation of following roads undercrossing the proposed railroad track:

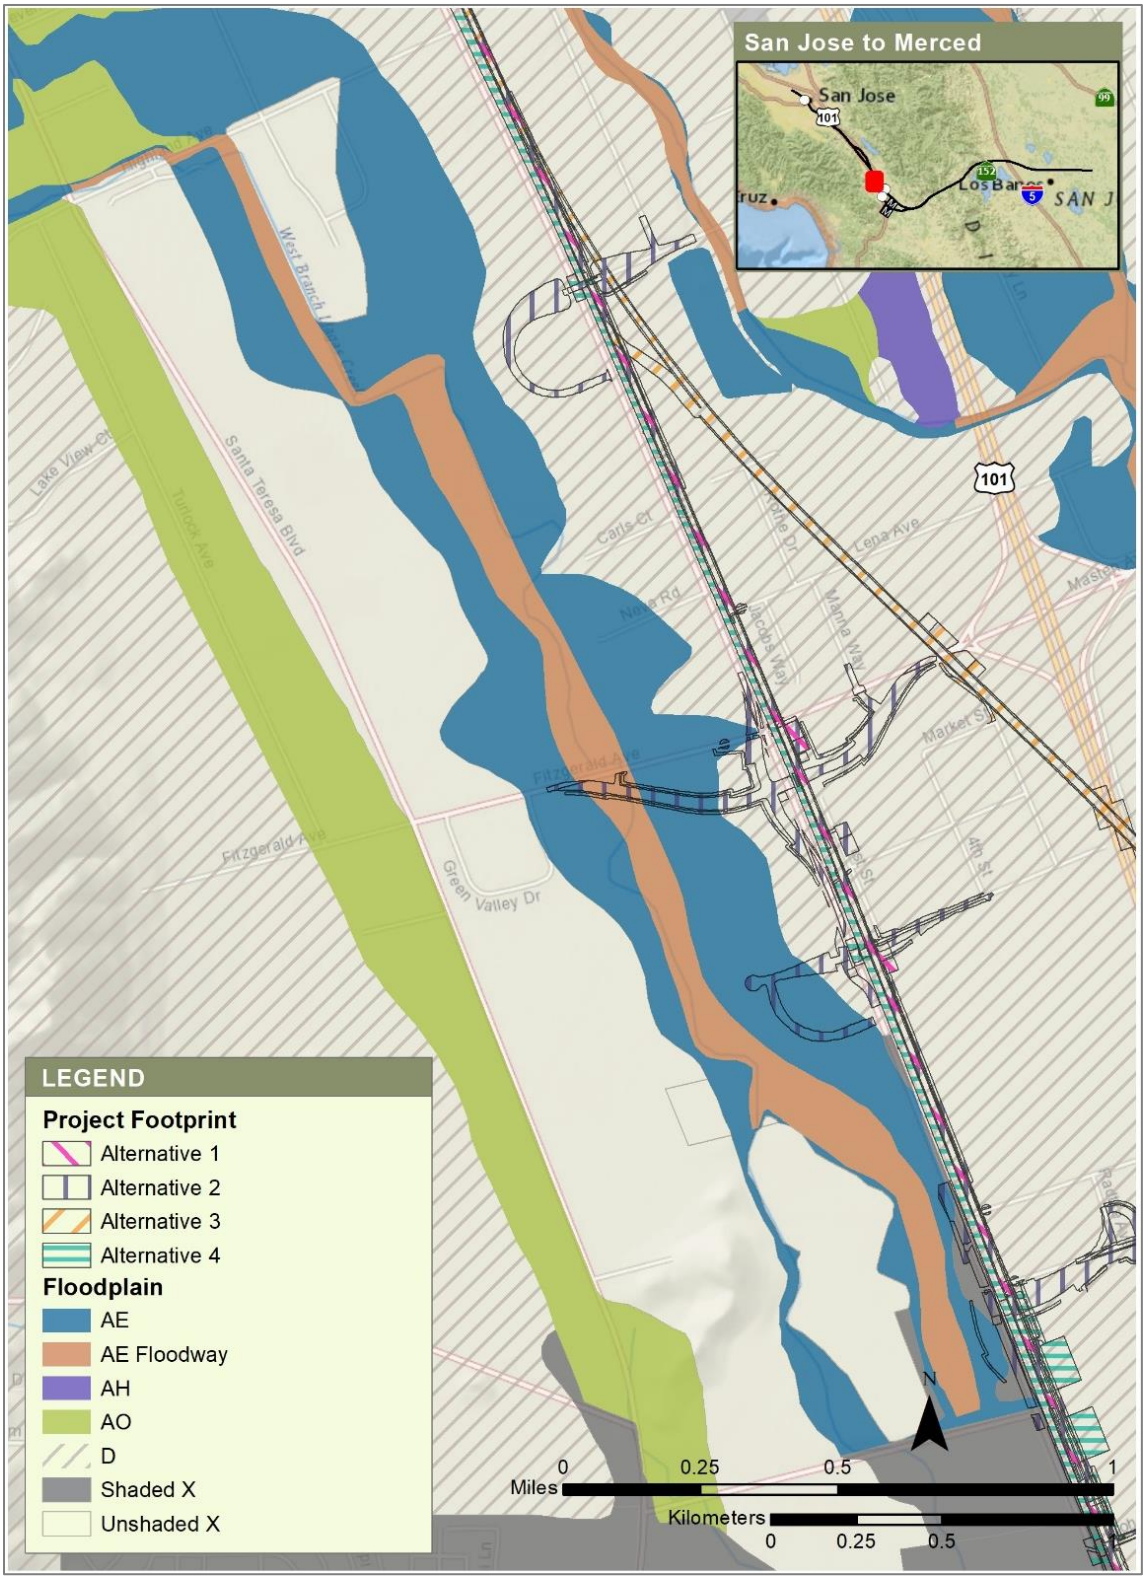
- Masten Avenue
- Rucker Avenue
- Buena Vista Avenue

This alternative would also require realignment and regrading of Monterey Highway, and portions of the realigned Monterey Highway would be in the existing 100-year floodplain for West Branch Llagas Creek.

3.9.1.4 Available Hydraulic Model

The FEMA effective hydraulic model was available to perform hydraulic analysis of this waterbody. Figure 3-37 shows the approximate limits of the FEMA effective hydraulic model and permanent project footprint for Alternative 2.

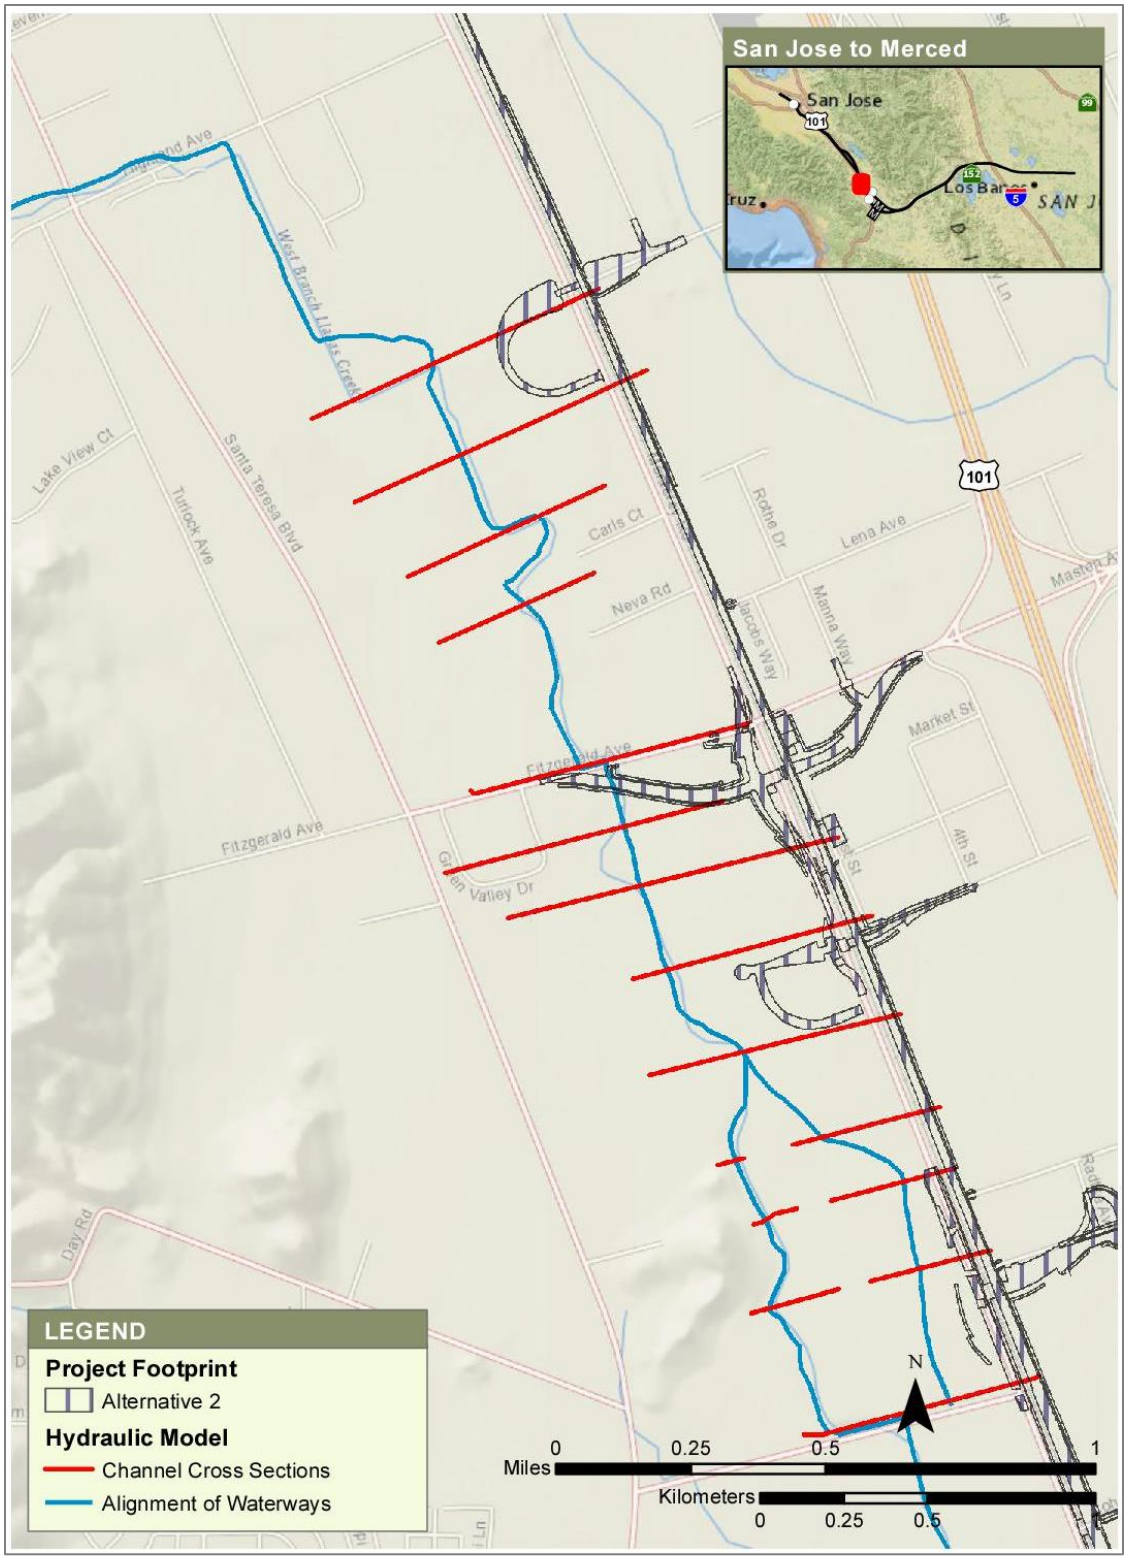
The SCVWD hydraulic model was not available for West Branch Llagas Creek. Therefore, hydraulic analysis was only performed using the FEMA effective hydraulic model.



Sources: FEMA 2009; Authority 2019

JANUARY 2019

Figure 3-36 West Brach Llagas Creek, Floodplain Map Zoomed to Project Location



Sources: FEMA 2018; Authority 2019. JANUARY 2019
Note: this figure does not display channel cross sections included in the hydraulic model.

Figure 3-37 West Brach Llagas Creek, Plan View of FEMA Effective Hydraulic Model with Project Footprint for Alternative 2

3.9.2 FEMA Effective Hydraulic Model

3.9.2.1 Overview of Hydraulic Model

The upstream and downstream limits of FEMA effective hydraulic model for West Branch Llagas Creek were at Highland Avenue (at approximately Station B1437+00) and at Day Road (at approximately Station B1581+00).

The limits of the channel cross sections included the existing railroad track on embankment. The proposed condition hydraulic included the proposed embankment section for Alternative 2. The detailed grading of channel excavation for the roadways in the footprint of the existing 100-year floodplain for West Branch Llagas Creek was not available. Therefore, the proposed condition hydraulic model did not include the proposed channel excavation for the roadway grade separation project part of Alternative 2. This model setup would be revised in the design phase of this project.

3.9.2.2 Water Surface Elevation

The modeling results for the Alternative 2 near the West Branch Llagas Creek are shown in Table 3-19. The outputs for Alternative 2 did not show increases in 100-year flood profile near the West Branch Llagas Creek between West San Martin Avenue on north and Day Road on south.

Table 3-19 Hydraulic Modeling Results, West Branch Llagas Creek, Alternative 2

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Day Road	160	229.5	229.2	229.2	0.0
At Santa Clara Avenue	1,375	240.5	241.5	241.5	0.0
At Fitzgerald Avenue	1,375	244.3	246.9	246.9	0.0

Elevations are rounded to the nearest 0.1 foot.
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

3.10 Llagas Creek (East of Gilroy)

3.10.1 Background Information

3.10.1.1 Floodplain Location

Llagas Creek flows through San Martin, Morgan Hill, and Gilroy. West Little Llagas Creek, Madrone Channel, and East Little Llagas Creek meet to form Upper Llagas Creek (Authority 2011a). Buena Vista Avenue divides Upper and Lower Llagas Creek. Lower Llagas Creek meets with West Branch Llagas Creek at SR 152 before it drains to the Pajaro River.

Llagas Creek east of Gilroy would require a permit process NRCS similar to the USACE Section 408 review and approval process.

3.10.1.2 FEMA Floodplain

According to the FEMA FIRM Panel Number 060685C0641H and 060685C0643H (FEMA 2009), the main channel of Llagas Creek in the project footprint is identified as Zone AE and a floodway (Figure 3-38). Llagas Creek at this location has levees on both sides of the main channel. The levees along the western bank are recognized by FEMA and appear in the FIRM #06085C0643H (FEMA 2009). The width of the effective Zone AE floodplain and floodway measured along the proposed railroad alignment for Alternative 3 is approximately 300 feet.

Llagas Creek east of Gilroy is outside of the Upper Llagas Flood Protection Project. There would be no changes to the channel geometry in this location, but changes in the flooding pattern would change the extents of the 100-year floodplain in the project footprint. The main channel of Llagas Creek would remain as Zone AE floodplain, but the width of the future Zone AE floodplain measured along the railroad alignment for Alternative 3 would change to approximately 330 feet (Figure 3-39).

Llagas Creek east of Gilroy in the project footprint is recognized as a floodway. Therefore, the project cannot raise the 100-year flood profile of Llagas Creek at East of Gilroy.

3.10.1.3 Project Alternatives in the FEMA Floodplain

The project footprint for Alternative 3 is in the existing 100-year floodplain for Llagas Creek at East of Gilroy (Figure 3-38). The Upper Llagas Flood Protection Project would change the limits of the 100-year floodplain of Llagas Creek in the east of Gilroy (Figure 3-39), and the project footprint for Alternative 3 would still be within the modified 100-year floodplain. The permanent impact areas for the remaining three project alternatives are outside of the limits of the existing FEMA 100-year floodplain of Llagas Creek at East of Gilroy.

Alternative 3 would entail a new railroad bridge over Llagas Creek from approximately station 1736+00 to 1744+50. The proposed railroad bridge crossing would be located approximately 2,700 feet upstream (north) of the existing SR 152 bridge over Llagas Creek. The proposed pier columns in the main channel of Llagas Creek would obstruct the flood flow and could potentially increase the profile of the floodplain and floodway. The project would entail widening the channel by offsetting the levees to the outside to maintain the existing floodplain and floodway profile of Llagas Creek.

3.10.1.4 Available Hydraulic Model

The FEMA effective hydraulic model and SCVWD hydraulic model were available for this waterbody. Figure 3-40 shows the approximate limits of the FEMA effective hydraulic model with the project footprint for Alternative 2. Figure 3-41 shows the limits of the SCVWD hydraulic model with the project footprint for Alternative 2.

The FEMA effective hydraulic model provided does not include up-to-date available information that were included in the SCVWD hydraulic model. Therefore, the SCVWD hydraulic model was used to evaluate the project's potential impacts.

JANUARY 2019

Figure 3-41 Llagas Creek (East of Gilroy), HEC-RAS Channel Cross Sections at Project Location

3.10.2 FEMA Effective Hydraulic Model

3.10.2.1 Overview of Hydraulic Model

The upstream and downstream limits of Llagas Creek east of Gilroy in the FEMA effective hydraulic model were approximately 3,400 feet upstream of Buena Vista Avenue Bridge (approximately 20,600 feet upstream of the proposed railroad bridge) and approximately 1,800 feet downstream of the Southside Drive Bridge (approximately 9,500 feet downstream of the proposed railroad crossing).

The channel width from the FEMA FIRM is approximately 400 to 500 feet (Figure 3-40), but the channel width of the FEMA effective hydraulic model at project location is approximately 12,000 feet. The footprint of hydraulic model includes Llagas Overbank on west and Zone A SHFA on east. Therefore, the setup of the FEMA effective hydraulic model would allow flood flow interaction between three independent floodplains. In addition, the current effective FEMA hydraulic model for Llagas Creek at the project location does include the changes to Llagas Creek and its tributaries resulting from SCVWD's Upper Llagas Creek Flood Protection Project.

3.10.2.2 Water Surface Elevations

The modeling results for Alternative 3 with the proposed creek widening are shown in Table 3-20. The outputs from hydraulic analysis showed the proposed Alternative 3 bridge would not increase the 100-year flood profile of Llagas Creek.

Table 3-20 Hydraulic Modeling Results, Llagas Creek (East of Gilroy), Alternative 3 with Creek Widening

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At State Route 152 Bridge	5,800	183.8	179.9	179.9	0.0
At proposed railroad bridge for Alternative 3	6,300	188.7	191.1	191.1	0.0
At Gilman Rd	6,300	196.8	196.2	196.2	0.0

Elevations are rounded to the nearest 0.1 foot
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

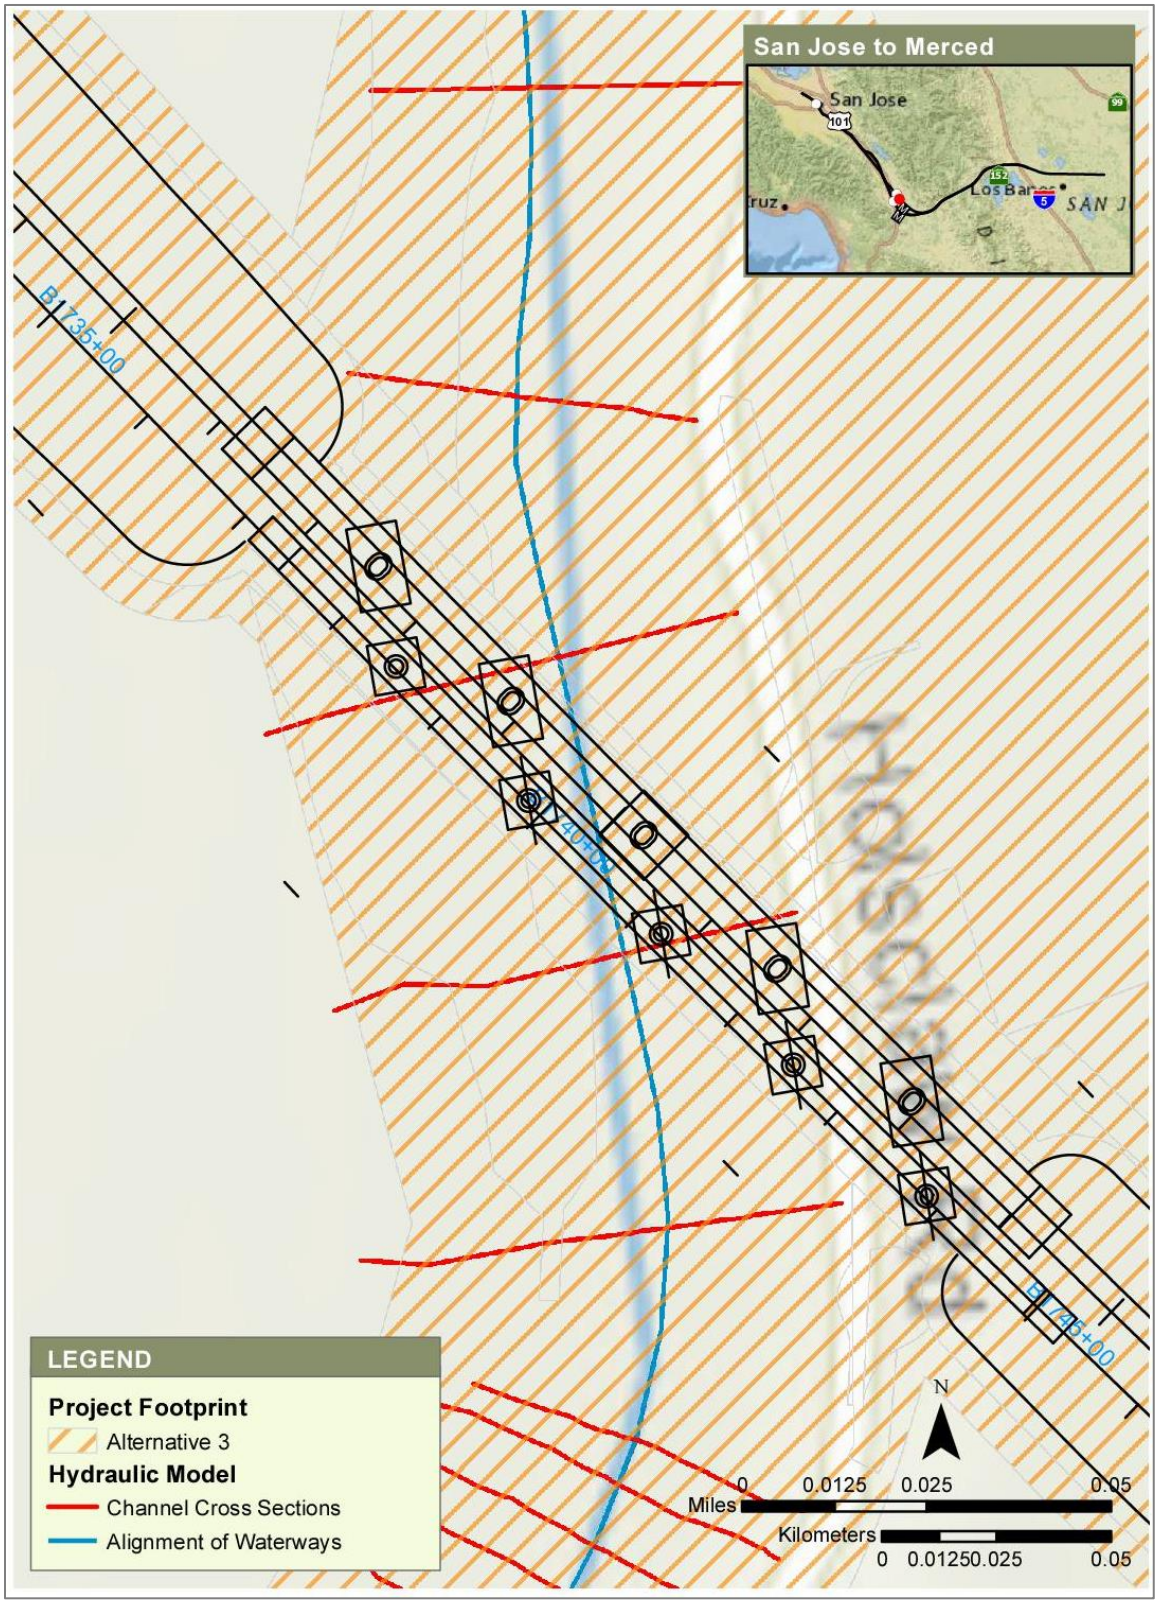
The current effective FEMA hydraulic model allow interaction between existing 100-year floodplain for Llagas Creek mainline, Llagas Overbank Flow on west, and Zone A floodplain on east of Llagas Creek mainline, even though FEMA FIRM does not show interaction between these three floodplains. Therefore, the outputs from the hydraulic analysis of the existing condition and Alternative 3 may not accurately represent the existing and proposed site conditions during the 100-year storm event, assuming Upper Llagas Flood Protection Project is completed prior to the beginning of construction for the HSR project. Therefore, hydraulic analysis was also performed using the hydraulic model of Llagas Creek and tributaries provided by SCVWD, and outputs from the SCVWD hydraulic model was used to evaluate the project's potential impacts on the existing 100-year floodplain.

3.10.3 SCVWD Hydraulic Model

3.10.3.1 Overview of Hydraulic Model

The SCVWD hydraulic model of Llagas Creek at East Gilroy (Figure 2-12) is same as the hydraulic models of Llagas Creek discussed in Section 3.6.3, SCVWD Hydraulic Model, (Llagas Creek near San Martin) and Section 3.7.3, SCVWD Model (Llagas Creek at East San Martin Avenue).

According to the preliminary bridge design for Llagas Creek bridge for Alternative 3, four piers would be inside the footprint of the hydraulic model and three piers would be inside the FEMA designated floodway (Figure 3-41). The three piers inside the designated floodway and one pier on outside of the western levee are included in the proposed condition hydraulic model for Alternative 3 (Figure 3-42). To represent the creek widening near the project footprint, the levees at the proposed bridge crossing in the hydraulic model were set back up to 50 feet to balance the potential floodplain and floodway impacts from the proposed pier columns inside the main channel of Llagas Creek.



Sources: SCVWD 2015b; Authority 2019 JANUARY 2019

Figure 3-42 Llagas Creek (East of Gilroy), HEC-RAS Channel Cross Sections, Zoomed to Proposed Llagas Creek Bridge for Alternative 3

3.10.3.2 Water Surface Elevations

The modeling results for Alternative 3 with the proposed creek widening are shown in Table 3-21. The proposed bridge piers for Alternative 3 in the main channel of Llagas Creek with the proposed creek widening would raise the 100-year WSE of Llagas Creek by 0.4 foot or less. HYD-MM#2, Maintain Existing 100-year Water Surface Elevations of the Llagas Creek Floodway near Holsclaw Road in East Gilroy, would be implemented to mitigate the impact of the bridge piers on the floodway. Mitigation could potentially include, but is not necessarily limited to, the following design solutions: optimizing the design of the piers supporting the proposed bridge or relocating the piers; relocating the existing levee in order to establish a wider channel and floodplain; and/or dredging the channel.

Table 3-21 Hydraulic Modeling Results, Llagas Creek (East of Gilroy), Alternative 3 with Creek Widening

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At confluence with West Branch Llagas Creek	8,248	189.9	180.6	180.6	0.0
At proposed railroad bridge for Alternative 3	8,248	191.6	191.2	191.6	0.4
At Gilman Rd	8,248	195.9	193.6	193.7	0.1

Elevations are rounded to the nearest 0.1 foot
cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation

3.10.3.3 Water Surface Elevations, Future SCVWD Hydrologic Condition

According to SCVWD, the design flow rate of 8,248 cubic feet per second (cfs) used in their hydraulic model accounts for escape flows from Llagas Creek upstream of the project location. The future flood control project on lower Llagas Creek, following the Upper Llagas Flood Protection Project, would allow Llagas Creek to fully convey the 100-year flow, which would be approximately 17,800 cfs at the project location (SCVWD 2018g).

During the meeting in April, 26, 2018, SCVWD requested the Authority to design proposed Llagas Creek Bridge for Alternative 3 to handle the future 100-year flood flow rate of 17,800 cfs at the project location without raising the current 100-year flood profile of Llagas Creek. The preliminary hydraulic analysis for Alternative 3 with additional channel widening was performed o to show that the proposed Alternative 3 bridge over Llagas Creek has sufficient opening width to accommodate future 100-year flow of 17,800 cfs and without raising the current 100-year flood profile shown in the hydraulic model. In this conceptual future condition for Alternative 3, the channel cross sections of Llagas Creek from upstream of the proposed HSR Alternative 3 bridge and confluence with West Branch Llagas Creek was widened approximately 70 to 90 feet and with channel excavation between bridge upstream face to the existing drop structure.

The outputs from the hydraulic analysis for Alternative 3 in the future scenario with additional modifications to the main channel of Llagas Creek showed that proposed bridge opening is sufficient to convey the future 100-year flow of 17,800 cfs without raising the flood profile from the 100-year flood profile based on flow rate of 8,248 cfs.

3.11 Llagas Overbank (East of Gilroy)

3.11.1 Background Information

3.11.1.1 Floodplain Location

Llagas Creek flows through San Martin, Morgan Hill, and Gilroy. West Little Llagas Creek, Madrone Channel, and East Little Llagas Creek meet to form Upper Llagas Creek (Authority 2011a). Buena Vista Avenue divides Upper and Lower Llagas Creek. Lower Llagas Creek meets with West Branch Llagas Creek at SR 152 before it drains to the Pajaro River.

3.11.1.2 FEMA Floodplain

The FEMA FIRM Panel Numbers 06085C0637H, 06085C0641H, and 06085C0643H (FEMA 2009) shows overbank flood flows from Llagas Creek forms shallow overland flow traveling parallel to Llagas Creek approximately 2,000 to 3,000 feet west of the mainline Llagas Creek. The overbank flood flow from are designated as Zone AO, Zone AE, and floodway (Figure 3-43).

The 100-year flood elevation of the Llagas Overbank with the project footprint varies from approximately 205 feet NAVD 88 at the proposed HSR access road located approximately 2,000 feet upstream (north) of Leavesley Road crossing to approximately 185 feet NAVD 88 at Gilman Road.

The Llagas Overbank in the project footprint is recognized as a floodway in the current effective FEMA FIRM. Therefore, the project cannot raise the 100-year flood profile of Llagas Overbank.

SCVWD's Upper Llagas Flood Protection Project would modify the existing floodplain/floodway footprint of Llagas Overbank (Figure 3-44). With completion of Upper Llagas Flood Protection Project, Llagas Overbank would not be classified as outside of the 100-year floodplain.

3.11.1.3 Project Alternatives in the FEMA Floodplain

The project footprints for all four project alternatives are in the existing 100-year floodplain for Llagas Overbank.

Alternatives 1, 2, and 4 propose a traction power switch station on Gilman Road would be in the limits of the existing 100-year floodplain. The base flood elevation (BFE) shown in the FEMA FIRM in the project footprint for Alternatives 1, 2, and 4 varies from 190 to 191 feet NAVD 88.

Alternative 3 would entail a new embankment segment over Llagas Overbank. Stations B1651+00 to B1684+00 and stations B1693+00 to B1720+00 would be inside the existing FEMA 100-year floodplain. Equalizers are proposed to maintain the existing flood pattern shown in the FEMA FIRM.

3.11.1.4 Available Hydraulic Models

FEMA effective hydraulic model was available to perform hydraulic analysis of this waterbody. Figure 3-45 shows the approximate limits of the FEMA effective hydraulic model with the project footprint for Alternatives 1, 2, and 4. Figure 3-46 shows the limits of the FEMA effective hydraulic model with the project footprint for Alternative 3. The SCVWD hydraulic model of Llagas Creek and tributaries for Upper Llagas Flood Protection Project did not include Llagas Overbank.

The hydraulic analysis was performed using FEMA effective hydraulic model. The hydraulic analysis outputs would not be used to evaluate the project's potential impacts on the 100-year floodplain, because Llagas Overbank would not be classified as 100-year floodplain after completion of the Upper Llagas Flood Protection Project.

3.11.2 FEMA Effective Hydraulic Model

3.11.2.1 Overview of Hydraulic Model

The upstream and downstream limits of Llagas Overbank in the FEMA effective hydraulic model were approximately 1,300 feet upstream of Buena Vista Avenue and approximately 1,800 feet downstream of the Southside Drive Bridge.

The proposed traction power switching station for Alternatives 1, 2, and 4 that is located inside the existing 100-year floodplain was represented in the hydraulic model by adding the flood flow obstruction with the same footprint as the proposed traction power switching station.

The proposed embankments for Alternative 3 that are in the footprint of the hydraulic model were represented using the obstruction feature equivalent to the footprint of the proposed structures. The width of obstruction assigned in channel cross sections varies from approximately 300 to 1,700 feet.

3.11.2.2 Water Surface Elevation

The modeling results for the Alternatives 1, 2, and 4 and Alternative 3 are shown in Table 3-22 and Table 3-23. The outputs for Alternatives 1, 2, and 4 did not show increases in 100-year flood profile of Llagas Overbank. The outputs for Alternative 3 showed elevation increase up to 0.3 foot in the project vicinity.

Table 3-22 Hydraulic Modeling Results, Llagas Overbank, Alternatives 1, 2, and 4

4 COMBINED ONE- AND TWO-DIMENSIONAL HYDRAULIC MODELING

4.1 Hydrology

The FEMA and SCVWD combined one- and two-dimensional HEC-RAS models used to perform existing and proposed condition hydraulic analyses included the hydrographs for the 100-year storm event. The hydrographs included in the hydraulic model are discussed in detail in each of the subsections “Inflow Hydrograph for Hydraulic Analysis”, for each floodplain.

4.2 Hydraulic Model Assumptions

The assumptions for all of the one-dimensional hydraulic model discussed in Section 3.3, general Hydraulic Model Assumptions, are also applicable for the combined one- and two-dimensional unsteady-state hydraulic models. The modeling assumptions that are specific to each hydraulic model are discussed in each of the Overview of the Hydraulic Model subsections for each floodplain.

4.3 Los Gatos Creek

4.3.1 Background Information

4.3.1.1 Floodplain Location

Los Gatos Creek runs 24 miles through Santa Clara Valley’s Guadalupe River watershed from the Santa Cruz Mountains, just south of Loma Prieta peak, north through the Santa Clara Valley until it reaches its confluence with the Guadalupe River in downtown San Jose (Authority 2011a). The Guadalupe River then continues to San Francisco Bay.

4.3.1.2 FEMA Floodplain

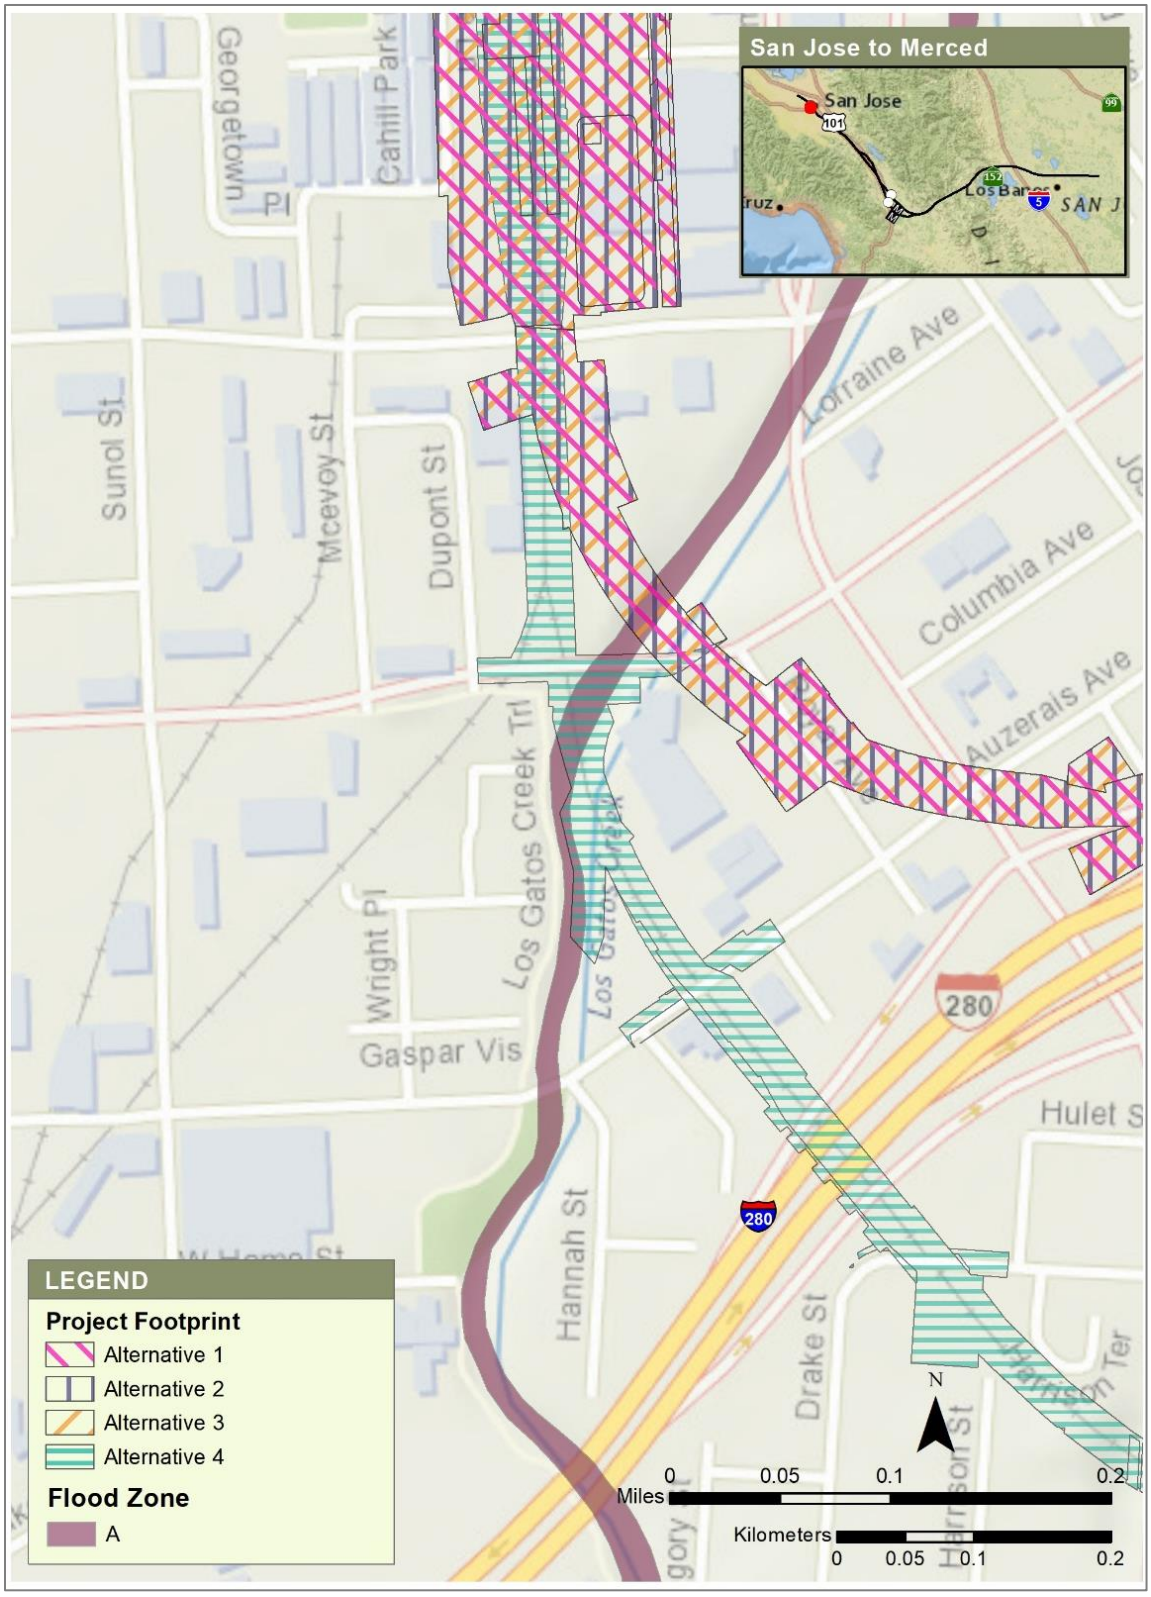
According to the FEMA FIRM Panel No. 60685C0234H (FEMA 2009), Los Gatos Creek in the project footprint is identified as Zone A (Figure 4-1). The FEMA FIRM does not show overbank flood flows in the project vicinity. The width of the Zone A measured along proposed track alignment is approximately 70 feet for Alternatives 1, 2, and 3 and approximately 130 feet for Alternative 4.

4.3.1.3 Project Alternatives in the FEMA Floodplain

The project footprints for Alternatives 1, 2, and 3 overlap with the existing 100-year floodplain for Los Gatos Creek. However, the proposed viaduct segment supported by pier columns for Alternatives 1, 2, and 3 would span over Los Gatos Creek and the proposed pier columns supporting the viaduct would be constructed outside the limits of the existing Zone A floodplain. The proposed railroad track profile over Los Gatos Creek would be approximately 60 feet above the existing channel bank elevation of Los Gatos Creek and would not be in contact with the 100-year flood flow as shown in the FEMA FIRM.

Alternative 4 proposes blended at-grade track using the railroad track currently used by Caltrain and UPRR, constructed in 2017. The HSR train would share the existing railroad bridge over Los Gatos Creek with Caltrain and UPRR. The modifications to the existing bridge structure are not proposed in this project alternative.

For all four project alternatives, no changes are proposed inside the existing FEMA 100-year floodplain of Los Gatos Creek.



Sources: FEMA 2009; Authority 2019

JANUARY 2019

Figure 4-1 Los Gatos Creek, FEMA FIRM Overlay with Project Footprints for Alternatives 1, 2, 3, and 4

4.3.1.4 Available Hydraulic Model

Los Gatos Creek in the project vicinity is identified as Zone A, which is assigned to floodplains determined by approximate methods. In addition, the date of the current effective FEMA FIRM (2009) is before the construction of the existing bridge in the year 2017, which would be used as the blended railroad track for HSR in Alternative 4. Therefore, the hydraulic analysis using FEMA's effective hydraulic model was not performed for Los Gatos Creek.

The more recent SCVWD hydraulic model was documented in this study. Figure 4-2 and Figure 4-3 shows the limits of the SCVWD hydraulic model and project footprint for Alternatives 1, 2, 3 and Alternative 4 at Los Gatos Creek, respectively.

4.3.2 SCVWD Hydraulic Model

4.3.2.1 Overview of Hydraulic Model

The upstream and downstream limits of Los Gatos Creek included in the hydraulic model were immediately downstream of Vasona Park Road Bridge in Vasona Reservoir (approximately 37,860 feet upstream of existing Caltrain/UPRR bridge over Los Gatos Creek) and confluence with Guadalupe River (approximately 4,100 feet downstream of the proposed HSR viaduct over Los Gatos Creek).

The two-dimensional mesh included in the hydraulic model used to represent the overbank flood flows, included areas roughly bounded by I-280 on south, I-87 on east, West Taylor Street on north, and The Alameda/Race Street on west. The area of the two-dimensional mesh included in the hydraulic model is approximately 836 acres.

The outputs from the existing condition hydraulic analysis showed that the existing railroad bridge over Los Gatos Creek would be overtopped during the 100-year storm event.

The proposed pier columns for Alternatives 1, 2, and 3 is located outside of the limits of the Los Gatos Creek main channel represented in one-dimensional riverine model. The hydraulic model for Alternatives 1, 2, and 3 did not make any modifications to the model inputs in the one-dimensional riverine component.

The proposed pier columns for Alternatives 1, 2, and 3 are within the limits of the two-dimensional mesh included in the hydraulic model, which represents the extents of the overbank flood flows from Los Gatos Creek within the model limits. The Manning's roughness coefficient of 1.0 was assigned in the footprint of the proposed piers columns for Alternatives 1, 2, and 3 to represent the additional obstruction from the proposed pier columns in the overbank area.

Alternative 4 does not proposed any improvements to the existing Los Gatos Creek bridge. Because detailed design of the removal/replacement Bird Avenue undercrossing proposed in this alternative is not available, hydraulic analysis for Alternative 4 was not performed in this phase of the proposed project.

4.3.2.2 Inflow Hydrograph for Hydraulic Analysis

According to SCVWD, flow hydrographs from the 2009 USACE Guadalupe Hydrology Report were used in the Los Gatos Creek HEC-RAS model (SCVWD 2018c). There were 11 locations in the hydraulic model with assigned inflows. The peak 100-year flows at each inflow location are summarized in Table 4-1. The inflow locations in the hydraulic model are shown in Figure 4-4.

Table 4-1 Peak 100-year Inflows into Los Gatos Creek Hydraulic Model

Location	Distance from Existing Railroad Bridge[1]	Peak 100-year Inflow (cfs)
RS 41962.09	37,860 feet upstream	7,730
RS 36755.72	32,660 feet upstream	511
RS 30400	26,300 feet upstream	130
RS 24499.3	20,400 feet upstream	130
RS 19915.39	15,820 feet upstream	107
RS 12899.16	8,800 feet upstream	107
RS 12591.04	8,490 feet upstream	107
RS 5087.607	990 feet upstream	267
RS 3953	150 feet downstream	36
RS 3363.051	740 feet downstream	36

Source: SCVWD 2018c JANUARY 2019

Figure 4-4 Inflow Locations in the SCVWD Hydraulic Model of Los Gatos Creek

4.3.2.3 Water Surface Elevations, Main Channel

The outputs from the existing condition and Alternatives 1, 2, and 3 are shown in Table 4-1. The outputs from hydraulic analysis shows the proposed pier columns for Alternatives 1, 2, and 3 placed in two-dimensional mesh area of the hydraulic model would not have an impact on the 100-year flood profile of Los Gatos Creek in the main channel.

Because there were minimal impacts on the existing 100-year floodplain, the existing railroad bridge would remain overtopped during 100-year storm event for Alternatives 1, 2, and 3. Alternative 4 does not propose any improvements to the existing Los Gatos Creek bridge; the existing railroad bridge that would be shared by HSR, Caltrain, and UPRR would remain overtopped during 100-year storm event.

Table 4-2 Hydraulic Modeling Results, Los Gatos Creek, Alternatives 1, 2, and 3

Location	Flow Rate (cfs)	Channel Bank Elevation (feet NAVD 88)	WSE—Existing Condition (feet NAVD 88)	WSE—Proposed Condition (feet NAVD 88)	Change in WSE (feet)
At Confluence with Guadalupe River	7,700	81.3	78.2	78.2	0.0
At proposed HSR viaduct crossing (66+00)	7,900	99.6	99.6	99.6	0.0
At exist Railroad Bridge	7,630	98.9	101.2	101.2	0.0
At Auzerais Avenue Bridge	8,030	103.7	105.9	105.9	0.0
At I-280 Bridge	8,260	109.2	109.5	109.5	0.0

cfs = cubic feet per second
NAVD 88 = North American Vertical Datum of 1988
WSE = water surface elevation
Elevations are rounded to the nearest 0.1 foot.
HSR = high=speed rail
I = Interstate
Flow rate shown in this table is for flood flows remaining inside the main channel, and is rounded up to the nearest 10 cfs.

4.3.2.4 Water Surface Elevations, Overbank Area

The outputs from the hydraulic analysis of the existing condition and Alternatives 1, 2, and 3 using the SCVWD hydraulic model showed overbank flood flows from Los Gatos Creek during 100-year storm event. The proposed pier columns for Alternative 1, 2, and 3 located outside of the main channel of Los Gatos Creek were in contact with the overbank flood flows.

The extents of the 100-year floodplain in the overbank area of the hydraulic model for the existing condition and Alternatives 1, 2, and 3 are shown in Figure 4-5. The proposed pier columns represented as areas with the Manning's roughness coefficient of 1.00 in the overbank areas represented by two-dimensional mesh showed no substantial changes to the extents of the 100-year floodplain.

JANUARY 2019

Figure 4-5 Extent of 100-Year Floodplain, Existing Condition and Alternatives 1, 2, 3, and 4

4.4 Guadalupe River and Tributaries

4.4.1 Background Information

4.4.1.1 Floodplain Location

Guadalupe River runs through downtown San Jose for 3 miles from I-280 to I-880 (Authority 2011a). The Guadalupe River's headwaters form in the Santa Cruz Mountains near the summit of Loma Prieta and Mount Umunhum. The river main stem begins on the Santa Clara Valley floor at the northern end of Lake Almaden, which is fed by Los Alamitos Creek and Guadalupe Creek, just downstream of Coleman Road in San Jose. From there, it flows north 14 miles through San Jose, emptying into San Francisco Bay at Alviso Slough. Historically, Guadalupe River was even shorter, originating several miles farther north at the downstream end of a large willow swamp that is now Willow Glen.

Guadalupe River in the project vicinity would be subject to the USACE Section 404 and 408 permitting process. The FEMA SFHA in the main channel of Guadalupe River that would be subject to USACE Section 404 and 408 permitting process is Zone A.

4.4.1.2 FEMA Floodplain

According to the FEMA FIRM Panel No. 60685C0234H (FEMA 2009), the main channel of the Guadalupe River in the project footprint is identified as Zone A with a width of approximately 150 feet (Figure 4-6). The FEMA FIRM also shows overbank flood flows from Guadalupe River and tributaries that are identified as Zone AO and AH (Figure 4-6 and Figure 4-7). The FEMA FIRM shows overbank flood flows from Canoas Creek overtopping the existing Caltrain track between Almaden Expressway and Curtner Avenue Bridges over the existing railroad track (Figure 4-7).

4.4.1.3 Project Alternatives in the FEMA Floodplain

The project footprints for all project alternatives are in the existing 100-year floodplain for Guadalupe River and Tributaries.

Under Alternatives 1, 2, and 3, a viaduct segment supported by pier columns would span the Guadalupe River and run along the top of the western channel bank. All project alternatives are identical near the Guadalupe River crossing. The proposed pier columns for the viaduct segment are inside FEMA SFHA Zones A, AO and AH.

Under Alternative 4, HSR would share the corridor with UPRR and Caltrain and would construct a new at-grade track adjacent to the existing track. Near the Guadalupe River bridge crossing, Alternative 4 is proposing a new single-track bridge structure over I-280, SR 87, and Guadalupe River on the south side of the existing bridge structure. The existing railroad track over I-280, SR 87, and Guadalupe River would remain. It also proposes to remove and replace existing underpasses for Bird Avenue and Delmas Avenue.

The FEMA FIRM shows that the overbank flow from Canoas Creek is overtopping the existing railroad track (Figure 4-7). The FEMA SHFA at this location is AH with an elevation of 131 feet NAVD 88.

The profile of the proposed railroad track for Alternatives 1, 2, and 3 are at the same level or lower than the existing railroad track profile adjacent to the proposed tracks, and has locations where the top of rail elevation is lower than the FEMA 100-year WSE at this location. The current plan for all Alternatives 1, 2, and 3 does not show any proposed hydraulic features to prevent the flooding on proposed HSR track during 100-year storm event. Therefore, portions in the proposed railroad track for HSR Alternatives 1, 2, and 3 would be submerged during the 100-year storm event.

Alternative 4 would be sharing the existing railroad track with Caltrain and UPRR at this location, and would maintain the existing railroad track profile at this location. Because there would be no changes to the existing track profile, proposed railroad track for HSR at this location is subject to flooding during the 100-year storm event, as shown in the current effective FEMA FIRM. The

current plan for Alternative 4 does not show proposed hydraulic features to prevent the flooding on proposed HSR track during 100-year storm event. Therefore, the proposed railroad track for HSR Alternative 4 would be submerged during the 100-year storm event.

The vertical profile of the proposed railroad track would be controlled by the vertical clearance required at the Almaden Expressway and Curtner Avenue undercrossing and possess a constraint to the feasibility of raising the proposed railroad track to be raised above the existing FEMA 100-year flood elevation. Floodwalls have been incorporated into the project alternatives to prevent the proposed track to be flooded or overtopped during the 100-year storm event.

4.4.1.4 Available Hydraulic Model

The FEMA effective hydraulic model was not available because the existing floodplain is designated as Zone A, defined as FEMA SHFA determined by approximate methods.

The hydraulic model provided by SCVWD was available for this waterbody and was used to perform hydraulic analysis to determine project's potential impacts on the existing floodplain.

Figure 4-8 and Figure 4-9 show the limits of the SCVWD hydraulic model and project footprint for Alternatives 1, 2, and 3 and Alternative 4, respectively, near the existing railroad bridge over Guadalupe River. Figure 4-10 and Figure 4-11 show the limits of the SCVWD hydraulic model and project footprint for Alternatives 1, 2, and 3 and Alternative 4, respectively, near Almaden Expressway and Curtner Avenue bridges over the existing railroad track.

The existing and proposed conditions of the 100-year flood profile of Guadalupe River near the existing and proposed railroad bridges over Guadalupe River were compared. The extents of the overbank flood flow in Almaden-Curtner area were also compared between existing and proposed conditions.

4.4.2 SCVWD Hydraulic Model

4.4.2.1 Overview of Hydraulic Model

The combined one- and two-dimensional hydraulic model of Guadalupe River and its tributaries provided by SCVWD was developed using the USACE HEC-RAS. The one-dimensional component of the SCVWD's HEC-RAS model refers to the main channel of Guadalupe River and tributaries (Canoas Creek and Ross Creek) represented by a series of channel cross sections and bridge crossings. The two-dimensional component of the SCVWD's HEC-RAS model refers to the overland floodplain area of Guadalupe River and tributaries represented by the computational mesh. The length and upstream/downstream limits of the floodplains included in the hydraulic model are summarized in Table 4-3.

Table 4-3 Floodplains included in Guadalupe River Hydraulic Model

Name of Floodplain	Reach Length (feet)	Location of Upstream Limit	Location of Downstream Limit
Guadalupe River	32,630	Approximately 500 feet downstream (north) of Coleman Road	Immediately upstream of I-280/SR 87 Interchange
Canoas Creek	39,000	At Cottle Road	Confluence with Guadalupe River
Ross Creek	25,920	At Blossom Hill Road	Confluence with Guadalupe River

Source: SCVWD 2018a
I = Interstate
SR = State Route

There were no changes to the setup of the SCVWD hydraulic model to perform the hydraulic analysis of existing condition.

The pier columns supporting the proposed viaduct segments along the Guadalupe River and at the Guadalupe River crossings for Alternatives 1, 2, and 3 were represented in the HEC-RAS model of the proposed condition. The proposed railroad bridge over Guadalupe River crossing for Alternatives 4 was represented in the HEC-RAS model of the by widening the existing railroad bridge over Guadalupe River located immediately downstream of the proposed railroad bridge.

The HEC-RAS model for Alternatives 1, 2, and 3 and Alternative 4 made adjustments to the model inputs in the two-dimensional mesh to include the proposed cut and fill, proposed structures within the existing FEMA 100-year floodplain, and project features that would minimize the potential for floodplain impacts. The full setup of the hydraulic model will be revised during the design phase of this project.

Floodwalls and equalizer culverts have been incorporated into Alternatives 1, 2, 3, and 4 to prevent the 100-year flood flow associated with the Canoas Creek/Guadalupe River overflow floodplain from overtopping the proposed HSR corridor near the overcrossings of Almaden Expressway and Curtner Avenue. Hydraulic analysis of the proposed condition with floodwalls and equalizers were also performed for Alternatives 1, 2, and 3 and Alternative 4.

In addition to the hydraulic analysis using a full model, a simplified one-dimensional hydraulic model (simplified SCVWD model), based on SCVWD's HEC-RAS model, was used for the hydraulic analysis of the Guadalupe River main channel for Alternatives 1, 2, 3, and Alternative 4 at the proposed railroad bridge crossing. The simplified SCVWD model was created by removing the two-dimensional model components and one-dimensional model components representing upstream tributaries from SCVWD's model. For this hydraulic model, new additional Guadalupe River channel cross sections were added to the model at the project location, based on the Santa

Clara County LiDAR data published in October 2020 (OCM Partners 2021). The new railroad bridge with channel grading, consistent with the existing design, was incorporated into the model to replicate the proposed condition.

4.4.2.2 Inflow Hydrograph for Hydraulic Analysis

There were 36 locations in the hydraulic model with assigned inflows. The peak 100-year flows at each inflow location are summarized in Table 4-4. The inflow locations in the hydraulic model are shown in Figure 4-12.

Table 4-4 Peak 100-Year Inflows into Guadalupe River and Tributaries Hydraulic Model

Floodplain Name	River Station in Hydraulic Model	Distance from Existing Railroad Bridge[1]	Peak Inflow (cfs)
Guadalupe River	104500	30,300 feet upstream	11,165
Guadalupe River	101450	27,250 feet upstream	137
Guadalupe River	98800	24,600 feet upstream	68
Guadalupe River	95900	21,700 feet upstream	68
Guadalupe River	94200	20,000 feet upstream	138
Guadalupe River	88000	13,800 feet upstream	275
Guadalupe River	87000	12,800 feet upstream	46
Guadalupe River	84005	9,800 feet upstream	45
Guadalupe River	82343	8,100 feet upstream	81
Guadalupe River	81773	7,570 feet upstream	45
Guadalupe River	78690	4,490 feet upstream	59
Guadalupe River	77944	3,740 feet upstream	81
Guadalupe River	75490	1,290 feet upstream	53
Guadalupe River	73691.23	500 feet downstream	105
Guadalupe River	72705.37	1,500 feet downstream	26
Canoas Creek	39008.19	46,800 feet upstream	475
Canoas Creek	38981.17	46,700 feet upstream	238
Canoas Creek	24395.26	32,220 feet upstream	93
Canoas Creek	22565.98	30,390 feet upstream	31
Canoas Creek	21618.92	29,440 feet upstream	196
Canoas Creek	21011.59	28,830 feet upstream	177
Canoas Creek	15301.56	23,120 feet upstream	177
Canoas Creek	13527.74	21,350 feet upstream	56
Canoas Creek	11053.71	18,880 feet upstream	56
Canoas Creek	8395.165	16,220 feet upstream	29
Canoas Creek	6665.77	14,490 feet upstream	36
Canoas Creek	6192.517	14,010 feet upstream	106
